Executive summary

Pesticides are used in agriculture to protect against insects, diseases and weeds that either attack the crop or compete for available resources. Although pesticide use is regulated in Canada, little data are collected on how they are actually used. The Crop Protection Survey was a voluntary survey designed to collect baseline data for the first time on quantities and types of pesticide and pest management practices used in 2005. This was a pilot project to determine the feasibility of collecting such information. This paper describes the methods used to collect the data and the process used to produce pesticide-use estimates for all Canadian apple production. Here are some of the major findings:

The majority of growers kept written records of pesticides applied to their orchards.

Growers rely heavily on chemical products to manage and control pests. They reported using pesticides for over 91.8% of total apple producing area.

A total of 924.7 tonnes of active ingredients for all types of pesticide were applied during the 2005 growing season. It is noteworthy that of the 528 tonnes of insecticide active ingredients applied in 2005, 464.7 tonnes (88%) was mineral oil, a low risk product used to prevent build up of pest populations.

Over half (57.1%) of the quantity applied was done to control insects, 40.8% to control diseases and 2.1% to control weeds. The average rate of application for the crop year for all active ingredients was relatively small for herbicides (1.28 kilogram per hectare) compared to 2.41 kilograms per hectare for fungicides and 5.97 kilograms per hectare for insecticides.

Over 90% of the total producing area was treated with insecticides, 86.6% with fungicides and 37.1% with herbicides.

Most of the treated area was either within or below the labelled rate of pesticide application.

Apple producers are diversifying the timing of their insecticide applications and in particular targeting insects at early stages of development when they are often easier to control with limited reliance on broad spectrum, relatively higher-risk insecticides. British Columbia and the Maritime Provinces showed the highest uptake of prevention-based integrated pest management (IPM) systems; Quebec and Ontario, where growers typically face more intense insect pest pressure had the lowest uptake.

The vast majority of the producing area with higher disease pressure was operated by growers planning to use prevention based management practices to control diseases. Practices needed to optimize the benefits of each fungicide application, while minimizing overall use, were adopted on more than two-thirds of the apple producing area. On the other hand, less than one-third of the area was simply sprayed by the calendar, a practice that often needlessly raises grower costs and environmental risks and contributes to the risk of triggering resistance to fungicides among disease pathogens. To manage the most prevalent diseases reported in 2005, growers were more likely to adopt advanced IPM practices than basic practices.

In order to help manage resistance of weeds, insects and disease to pesticides, the practices of reducing pest populations through non-chemical means were used on 35.6% of the producing area.

Canadian apple producers face a significant challenge in managing resistance, given that resistant weeds, insects and plant diseases are already present on about one-third of the producing area.

1 Introduction

Pesticides are used in agriculture to protect against insects, diseases and weeds that either attack the crop or compete for available resources. Pesticides are regulated in Canada by the Pest Control Products Act, which is administered by the Pest Management Regulatory Agency (PMRA) of Health Canada. Before they can be used in Canada, pesticides are evaluated against strict scientific criteria. The evaluation takes into consideration exposure and toxicity of the pesticides to humans and the environment, as well as the effectiveness of the pesticide for its intended purpose. Only pesticides that meet the standards set by the regulator are registered for use in Canada.

Although pesticide use is regulated in Canada, little data are collected on how they are actually used. Agriculture and Agri-Food Canada, in collaboration with PMRA, is working with agricultural stakeholders to reduce pesticide risks by assisting the development and adoption of lower risk pesticides and pest management practices. Questions that need to be answered before pesticide risks can be reduced include: How much pesticide is used? How is it applied? When is it applied? On what crop is it applied? What pest is being controlled? What pest population thresholds are used to trigger an application?

The Crop Protection Survey was designed and tested to collect data on these questions from apple, carrot and grape growers in Canada as a pilot project to determine the feasibility of collecting such information.

In Canada, apples are grown in areas where warm summers are complemented by mild winters. Major production areas include Ontario, Quebec, British Columbia and Nova Scotia which totalled 97.8% of the total producing area (Figure 1).

Source: Statistics Canada, Fruit and Vegetable Survey.

This paper describes the methods used to collect the data and the process used to produce pesticide-use estimates for all Canadian apple production. This is followed by a presentation of the results, including tables, graphs and discussion.

Section 2 describes the methodology. Section 3 presents the survey results. Sections 3.1 to 3.4 report results for pesticide use on selected orchards for the calendar year 2005, including how records were kept, how was made the decision to apply specific products, when, how and how much of each specific product was applied.

Sections 3.5 and 3.6 present information on spraying practices; weed, insect and plant disease pest management practices; and the most prevalent targeted weed, insect or plant disease. Also presented is the prevalence of pest pressures in 2005 compared to the previous five years.

Section 3.7 presents results about the perceived presence of possibly resistant pests.

Detailed statistical tables are included in Appendix A. The survey questionnaire is included in Appendix B.

2 Methodology

2.1 Data source

Results are based on the 2005 pilot survey on crop protection. This voluntary survey was designed to collect baseline data for the first time on quantities and types of pesticide and pest management practices used in 2005. This survey was conducted for Agriculture and Agri-Food Canada (AAFC), Environment Canada (EC) and Health Canada (HC). A total of 572 apple producers voluntarily participated in the survey conducted by Statistics Canada from January to March 2006. Growers provided information on their use of pesticides and other pest management practices during the 2005 growing season. Producers were asked to complete the survey with the help of a trained interviewer on the premises of farm operations. Surveying took place from the beginning of January to the end of March 2006. The survey questionnaire is presented in Appendix B.

The first two sections of the survey recorded information on the location, farm size, area devoted to apple production, varieties grown and orchard history. Most surveyed farms grew apples in more than one orchard and some operated a dozen or more. To reduce response burden and the time to complete the survey, one orchard was randomly selected from up to ten of the largest orchards operated by the farmer. All subsequent questions on pesticide use and pest management practices focused on this single orchard.

The survey was well received with an overall response rate of 89.9%.

2.1.1 Target population

The target population consisted of all active farms in Canada with sales of \$10,000 or more reported to the 2001 Census of Agriculture, which contributed to the top 95% of the total acreage of apple. Operational constraints led to the exclusion of certain types of farms: institutional farms (prisons, research stations, colleges), farms located on Indian reserves, small farms that contributed to the lowest 5% of the total acreage of each type of crop in each region, remote farms that could not be visited by interviewers within reasonable traveling distance and cost; and farms located in the Prairie Provinces, the Yukon, the Northwest Territories and Nunavut.

2.1.2 Sample selection

The survey frame consisted of the list of all active farms from the 2001 Census of Agriculture, updated with the acreages of apple operations for the subset of farm operations that also responded to the 2003, 2004 and 2005 Fruit and Vegetable Survey. The survey frame was divided into groups, or strata, defined by region and by size of operation based on acreage (large, medium and small operations).

Farms were randomly selected within each stratum. Large farms that contributed to a significant proportion of the provincial total apple area were all included in the sample. These farms were assigned a weight of one and thus represented no other farms in the target population but themselves.

A random sample of the medium and small farms was selected. These farms were assigned a weight greater than one since they represented other farms with similar characteristics.

Furthermore, each selected orchard had a specific weight based on the probability of a farm being selected for the sample and the proportion of the selected orchard compared to the total producing area of the selected farm. Weights were adjusted after data collection for non-response and they were used to estimate results to the target population.

2.2 Survey coverage

The survey was designed to cover 95% of the total producing area in each region (Maritime Provinces, Quebec, Ontario and British Columbia). Table 1 shows how representative the results are in terms of number of operations and producing area compared with results of the 2006 Census of Agriculture and the 2005 Fruit and Vegetable Survey. Overall, the Crop Protection Survey represented 37.0% of all apple growers in Canada. In terms of producing area, the survey covered 88.1%. The growers who reported using pesticides represented 86.5% of the total producing area. The questionnaires with valid and usable information about pesticide application accounted for 81.7% of all producing area and the selected orchards represented almost half of the total producing area.

Source: Statistics Canada, 2006 Census of Agriculture, 2005 Fruit and Vegetable Survey, 2005 Crop Protection Survey.

2.3 Pest management practices

A series of questions was asked about pest management practices used by apple growers on the selected orchards. Respondents were asked to identify the targeted pests, practices used to deal with the problems, expertise and information used for decision making, the basis for application decisions and whether pest pressure had changed over the last five years. Growers facing greater pest pressure were asked what they were planning to do in the next growing season to reduce the problem. Where applicable, the practices were grouped into two categories: dependent practices relying more on the use of pesticides (pesticide dependent practices) and those focusing more on prevention (integrated pest management practices).

To get a better idea of the uptake or importance of the adoption of the different practices¹, each answer was expressed into the producing area covered by multiplying the area of the selected orchard by its survey weight to estimate results to the target population. One limitation of this approach is the assumption that the grower who adopted a specific practice in the selected orchard also adopted this practice to all the other orchards that the grower operated.

2.4 Pesticide use estimation

The following section describes the different statistics related to pesticide-use estimates.

2.4.1 Treated area

For each combination of selected orchard and product application (or active ingredient)², the treated area was estimated using the total orchard area times the percentage of the orchard area treated. For each possible combination, the application used on the largest treated area was then retained as the maximum area treated over the growing season. The maximum treated area was then multiplied by the selected orchards' survey weight³. The total treated area was then calculated by summing up the weighted maximum area treated of all selected orchards for each active ingredient.

$$Treated_area = \sum_{f=1}^{F} Max \underset{a=1}{\overset{A}{=}} (Percent_Area_{a}) \times WeightF_{f}$$

where WeightF is the survey weight of the selected orchard *f*, $Percent_Area$ is the selected orchard area times the percent of the area that was treated during a single application *a*; Max is for the maximum value of percent area among all application (a) on the selected orchard; and *f* is the fth selected orchard in the survey sample.

2.4.2 Average number of applications

For each combination of selected orchard and active ingredient, the average number of applications was derived by adding the treated area of all applications over the growing season (or cumulative treated area) divided by the maximum area treated. A weighted average⁴ of all selected orchards surveyed was then calculated for each active ingredient.

2.4.3 Quantities of active ingredients applied

For each application, the quantity of active ingredient was calculated by multiplying the treated area by the normalized reported rate of application5. For each combination of selected orchard-active ingredient, the total quantity used was derived by adding up the quantity calculated for all applications over the growing season. These totals for each combination of selected orchard-active ingredient were then multiplied by the specific

^{1.} Counts of growers reporting a practice would not give a complete picture on the adoption of this practice as growers operate orchards of different sizes. For example, a practice may be significant in terms of the number of growers adopting it. However, if the majority operated small orchards, its importance may be much less significant once expressed in terms of the producing area covered by this practice.

^{2.} Each active ingredient was considered as one application for products that contain more than one active ingredient.

^{3.} Refer to section 2.1.2 for survey weight explanation. These weights were used to extrapolate results to the whole target population.

^{4.} Selected orchard weights adjust average to take into account the size of different selected orchards.

^{5.} Expressed in kilograms of active ingredient per hectare. Products in liquid form were converted into kilograms per hectare using percentage of guaranteed active ingredient and specific gravity.

selected orchard survey weight. The quantities for each active ingredient were then calculated by adding up the quantities for all selected orchards.

2.4.4 Average rates of application

For each combination of selected orchard and active ingredient, the cumulative treated area was estimated by summing up all treated areas over the growing season. The cumulative treated area was then multiplied by the selected orchard survey weight. For each active ingredient, the average rate of application was then estimated by dividing the total quantity of active ingredient applied (as calculated in 2.4.3) by the cumulative area treated.

2.4.5 Pesticide-use intensity

For each combination of selected orchard and active ingredient, the treated area was qualified as being below, within or above the labelled rate of application (three intensity categories). The totals for each combination of selected orchard-active ingredient-intensity category were then multiplied by the selected orchard survey weight. The treated area for each active ingredient was then calculated by adding up the treated area in each intensity category for all selected orchards. For each active ingredient, pesticide-use intensity was then expressed in percentage by dividing the total treated area by the cumulative treated area for each category.

3 Results

This section highlights significant findings related to the use of pesticides and other pest management practices used by apple growers in 2005. Detailed statistical tables are included in Appendix A.

3.1 Methods of keeping records of pesticide applications

Written records were kept on over three-quarters (78.7%) of the producing area (Figure 2), while 12.8% of the producing area had electronic records kept. No records were kept for 8.6% of the producing area. Regional differences were apparent, with British Columbia having the largest producing area (20.8%) with no records kept.

Figure 2 Format used to keep records of pesticides applied, selected provinces, apple producing area, 2005

3.2 Information kept in record keeping systems

For most of the producing area, records were kept for the product applied (91.9% of total producing area), the date of application (90.2%) and the rate of application (87.7%) (Figure 3). Targeted weed, insect or plant disease was recorded for just over half of the producing area. There were no significant regional differences with respect to the type of information recorded.

3.3 Pesticide application

Pesticides are important pest management tools for growers, as demonstrated in Figure 4 (Tables A.3 to A.7, Appendix A). For all selected provinces, growers reported using pesticides on over 91.8% of the total apple producing area. This proportion reached over 97% in the Maritime Provinces and Ontario, while it was 84.2% in British Columbia and 86.0% in Quebec. A limitation of these data is that organic farmers using strictly non-chemical pest control methods were not specifically identified in the sample selection prior to data collection. It is likely that organic growers were under-represented in this pilot survey.

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

A total of 924.7 tonnes of active ingredients included in insecticides, herbicides and fungicides were applied during the 2005 growing season on apple producing area. Over half (57.1%) of this total was applied to control insects, 40.8% to control diseases and 2.1% to control weeds.

Over 90% of the producing area was treated with insecticides, 86.6% with fungicides and 37.1% with herbicides. On average, insecticides and herbicides were applied 1.5 times during the season, while fungicides were applied more often (3.5 applications). The average rate of application for the crop year for all active ingredients was relatively small for herbicides (1.28 kilogram per hectare) compared to 2.41 kilograms per hectare for fungicides and 5.97 kilograms per hectare for insecticides (Table 3). Detailed information by province and active ingredient is presented in Appendix A, Tables A.3 to A.7.

3.4 Pesticide-use intensity

The following figures show that overall, most of the treated area was either within or below the labelled rate of application. No attempt was made to identify factors such as a severe insect, disease or weed infestation which may help to explain why a small portion of growers used a rate higher than the labelled rate. This type of analysis was beyond the scope of this report, but could be conducted in future research.

Figure 5 shows that most herbicide treatments (93.3%) were within or below the labelled rate of application. There was no significant difference across regions.

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Percentage of cumulative treated area.

Source: Statistics Canada, 2005 Crop Protection Survey.

Similarly, for insecticides, Figure 6 shows that 92.8% of insecticide treatments were within or below the labelled rate of application. There was a small difference across regions, with 15.4% of the insecticide treatments in British Columbia being higher than the labelled rate (Appendix A, Table A.13).

Figure 6 Insecticide-use intensity, selected provinces, apple producing area, 2005

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Percentage of cumulative treated area.

Source: Statistics Canada, 2005 Crop Protection Survey.

Figure 7 shows that most of the apple fungicide treatments (85.4%) were within or below the labelled rate of application. There were some significant differences across regions. In British Columbia, close to one-third (29.0%) of the fungicide treatments were above the labelled rate of application, while Quebec had the lowest percentage of fungicide treatments that were higher than labelled rates (6.6%).

3.5 Pesticide spraying practices

Pesticide spraying practices have an impact on how much of the pesticide applied reaches the intended targeted pests. In the survey, growers were given a list of practices that are commonly recommended as ways to reduce spray drift and increase the precision of applications. The list included five practices dealing with sprayer maintenance and design (e.g., use of shrouds or cones to direct sprays, replacing the nozzle every three years) and five practices dealing with how sprayers are used (e.g., sprayer speed, wind direction). Respondents were instructed to check all the practices used.

Growers indicated that six of these practices were used on 60% or more of the apple producing area, with four of these being used on 80% or more of the producing area. The adoption of advanced low-drift spray equipment and maintenance practices was lower, with two of the five practices being used on less than half the producing area. These practices are relatively more costly and growers may not see the short-term payoff in using these practices (Figure 8).

Among the specific practices used in the majority of spray operations, sprayers were operated at less than 16 km/hour on 93.2% of the producing area, 87.8% of the apple producing area was sprayed only when wind speeds were low and airblast direction was adjusted for targeted height on 83.3% of the apple area.

As shown in Appendix A Table A.14, producers in British Columbia were less likely to calibrate sprayers annually (67.2% of growers practiced annual calibration in British Columbia) than farmers in other provinces, likely reflecting differences in the total number of applications and pesticide expenditures. The relatively higher percentage of high-density orchards planted to dwarf trees in British Columbia allow growers to use low boom height sprayers on almost 78.6% of apple hectares, compared to less than 37.3% of hectares in the other provinces.

Figure 8 Spraying practices, selected provinces, apple producing area, 2005

3.6 Pest management practices

Canadian consumers expect high quality produce. This high quality produce is partly achieved by controlling crop pests. The most common tools available are pesticides, which include herbicides to control weeds, fungicides to control diseases and insecticides to control insects. Pesticides provide immediate results in a cost effective way. Growers make the best use of this pest management tool by applying the right amount, by timing their applications at specific pest development stages, by using different products in combination, or switching and rotating the family of products used over time. These practices will be referred to in this section as pesticide dependent practices.

Other tools are used by growers to control crop pests. Some more obvious tools include selecting pest resistant crop varieties and disease free stock. Other practices are less common, such as altering fertilizer or irrigation water levels and releasing or attracting beneficial organisms. These management practices have to be planned out and results may not be apparent for a couple of years. These practices will be referred to as prevention based practices.

3.6.1 Insect incidences and management practices

This section highlights results related to the incidence of insects and the management practices used by apple growers to control them.

3.6.1.1 Changes in insect incidences

Insect pest pressure varies from year to year and from region to region. Growers were asked if insects in 2005 were more, less or about equally prevalent, compared to the last five years. For the 2005 growing season, insect pressure was reported as "about the same" on 56.1% of the apple producing area (Figure 9). Insects were "much less or less" prevalent than in recent years on 29.6% of the producing area and "more or much more" prevalent on 14.3% of the producing area.

More than 90% of the producing area in Quebec had insect pest pressure that was either lower than or the same as the last five years. In contrast, a significant amount of the producing area in Ontario (18.8%) and in British Columbia (16.3%) experienced insect pest pressure that was higher than it had been in the last five years (Appendix A, Table A.15).

Figure 9 Insect incidence compared to the last five years, selected provinces, apple producing area, 2005

[■] Much less or less □ About the same ■ More or much more

3.6.1.2 Responses to greater insect pressure

Growers operating the orchards with "more or much more" insect pest pressure were asked what they plan to do in the next growing season in the hope of reducing their insect problems. Six practices were proposed, along with a box to identify "other" practices. Growers were instructed to check all the practices they planned to use.

Three of the listed practices involved more effective use and greater reliance on insecticides. Growers reported that on just under 60% of the producing area with greater insect pressure they plan to use two of the three pesticide-dependent actions (switch to a different insecticide, make an additional application), while 5.7% of the producing area would include a plan to increase rates of application (Figure 10).

Three other listed practices involved prevention-based integrated pest management (IPM) practices: scouting, use of forecasting systems and disruption of insect reproduction or development. Using these practices, growers know when insecticides need to be used and money is not wasted on needless applications. Growers reported plans to use two of these three tactics on more than 72% of the producing area with greater insect pressure and the third practice of disrupting insect reproduction or development on 62.9% of the producing area.

On almost the entire producing area (91.7%) operated by growers reporting to have "more" or "much more" insect problems compared to the last five years, growers planned to use prevention based practices in the future whereas 50% of this area was operated by growers who planned to apply an additional insecticide treatment to deal with future insect problems. Very little of the producing area under intense insect pressure was operated by growers rates of insecticide application in order to reduce insect problems in the future.

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having "more" or "much more" insect problems compared to the last five years. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.1.3 Most prevalent insects

Very few growers in Canada had to deal with a new insect pest in 2005 (Figure 11). Ontario had the highest incidence of new pests reported (14.3% of the producing area), while British Columbia and the Maritime Provinces had the lowest incidences (less than 8% of producing area).

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

The most prevalent insects that apple growers had to control on selected orchards in 2005 were the codling moth (mainly in British Columbia and the Maritime Provinces) and the oblique banded leaf roller (in Ontario and Quebec) (Figure 12 and Appendix A, Table A.18).

Figure 12 Most prevalent insect, selected provinces, apple producing area, 2005

3.6.1.4 Practices used to control growers' most prevalent insect

Growers were asked to indicate from a list of six practices the ones that they used to control their most prevalent insect. Two of the practices were dependent on pesticides and were related to the timing of applications, while the other four practices were prevention-based and reflect a commitment on the part of the grower to use biologically-based, IPM control methods. Timing insecticide applications at specific life stages of their most prevalent apple insect was used on 92.9% of the producing area. Prevention-based practices were used on 46.4% of producing area. Thirty percent of the producing area was operated with growers making attempts to attract beneficial insects, while 6.7% of the producing area had beneficial organisms released in an attempt to control the most prevalent insect (Figure 13).

More than 85.3% of the apple orchard area was treated with an insecticide at specific, targeted times during the growing season to manage the orchard's most prevalent insect. Just over half of the producing area was sprayed at different times throughout the growing season for the same pest.

These results show that apple producers are diversifying the timing of their insecticide applications and in particular, targeting insects at early stages of development when they are often easier to control with limited reliance on broad spectrum, relatively higher-risk insecticides. Over 37% of the producing area was sprayed with a product targeting early nymphs or eggs, or treated with an insecticide that disrupts larval or nymph development. Insecticides were sprayed to control adult insects on 24.0% of the producing area.

Overall, data show that growers in British Columbia and in the Maritime Provinces are more likely to use prevention-based IPM systems than the Central Provinces, where growers typically face more intense insect pest pressure. Growers deployed one or more of these four practices on more than half of the producing area in the Maritime Provinces and British Columbia (Appendix A, Table A.19). Furthermore, producers in British Columbia used each of the four practices on 19% or more of the producing area, including mating disruption on 47.0%. In the Maritime Provinces, growers taking steps to attract beneficial organisms used this practice on 40.8% of their producing area.

Figure 13 Practices to control the most prevalent insect, selected provinces, apple producing area, 2005

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having a significant insect problem. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.2 Disease incidences and management practices

3.6.2.1 Changes in disease incidences

Growers were asked if diseases in 2005 were more, less or about equally prevalent, as compared to the last five years. On half the producing area, growers reported that the incidence of disease (fungus, bacteria and mildew) was "about the same" in 2005 compared to the last five years. Prevalence was "much less or less" on 31.8% of the producing area and "more or much more" on 18.2% of the producing area (Figure 14).

Disease pressure was significantly higher in the Maritime Provinces for one-quarter of the producing area. Forty three percent of the producing area in Ontario had less disease pressure than in previous years.

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.2.2 Responses to greater disease pressure

Growers who faced "more or much more" disease were asked to choose from a list of practices that they planned to do to help reduce disease problems during the next growing season. Three of the listed practices related to better use of fungicides and three related to prevention-based management practices.

Over three-quarters (77.5%) of the producing area with more disease pressure was operated by growers who planned to use prevention-based management practices to control diseases. More than 63% of the producing area was operated by growers who planned to use forecasting systems or scouting in order to help control disease damage in the future. Altering soil fertility or water management was chosen less frequently as a practice that would reduce disease pressure, with 13.4% of the producing area where growers had plans for these practices (Figure 15).

For nearly half of the producing area, growers planned to switch to a different fungicide and for 35.3% of the producing area, growers planned to apply an additional fungicide to deal with future disease problems. About 15.9% of the producing area was planned for increased fungicide rates of application. Quebec growers stand out as a group that planned to use less pesticide-dependent practices and planned to rely more heavily on prevention-based practices as compared with the other provinces. (Appendix A, Table A.21).

Figure 15 Actions planned to reduce disease problems, selected provinces, apple producing area, 2005

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having "more" or "much more" disease problems compared to the last five years. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.2.3 Most prevalent diseases

Growers reported new plant diseases on 5.6% of the producing area in 2005 (Figure 16).

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

Apple scab, bacterial blight and mildew were the most prevalent diseases reported (Figure 17). By far the most prevalent disease reported was apple scab, which was a far bigger challenge in the Eastern provinces compared to British Columbia. This is likely due to climatic differences (Appendix A, Table A.23).

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.2.4 Practices used to control growers' most prevalent disease

All growers were asked to report tools or methods they or their advisors use to make decisions on when to apply fungicides to control their most prevalent disease. Six tools were listed along with a box to identify "other" practices. Growers were instructed to check all the tools they used.

Eighty six percent of the producing area was operated by growers who considered climatic conditions when making decisions about when to apply fungicides (Figure 18). Very few growers made decisions with the help of agricultural consultants (represented 7.0% of the producing area and accounted for nearly all of the "Other" answers). Practices needed to optimize the benefits of each fungicide application, while minimizing overall use, were adopted on more than two-thirds of the producing area (scouting and using forecasting models). Just under one-third of the producing area was sprayed on a fixed schedule (calendar spraying), a practice that often raises growers' costs and environmental risks and can contribute to the risk of triggering resistance to fungicides among disease pathogens.

Figure 18 Tools or methods to make decisions on when to apply fungicides, selected provinces, apple producing area, 2005

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having a significant disease problem. Source: Statistics Canada, 2005 Crop Protection Survey.

Growers were given a list of four basic IPM practices and three advanced IPM practices that are indicative of a heavy emphasis on prevention. They were asked to identify which practices they use to control their most prevalent disease.

Disease on 53.2% of the producing area was managed by growers making efforts to eliminate possible sources of disease inoculum, such as removing cull piles and pruning trees and host plants in nearby fields. Just under 37% of the producing area was managed with growers cleaning their equipment to reduce the risk of disease transport between locations (Figure 19). These basic IPM practices are recommended in all orchards, particularly in areas where plant diseases trigger the need for multiple fungicide applications, as is the case in the Ontario, Quebec and the Maritime Provinces.

The three more advanced IPM practices involve management of fertilizer rates and water applications to avoid either nutrient excesses (that can trigger a spike in disease organism populations), or impair plant defense responses (testing soil for micronutrients). Approximately 60% of the producing area was managed by growers who adjusted fertilizer rates to prevent excessive levels of nutrients in the root or foliage that could result in more disease. The soil was tested for micronutrient imbalances on 45.6% of the producing area. The degree of adoption of these practices shows that growers are willing to build more advanced preventive practices into their disease management systems.

Very few growers reported considering disease resistance or transplant disease when planting new trees. Only 11.6% of the producing area was planted with disease-free rootstock and 10.7% of the producing area was planted with a variety that had resistance to the most prevalent disease threat. This low percentage reflects the fact that many orchards were planted years ago when the most prevalent diseases were different.

Figure 19 Practices to control the most prevalent disease, selected provinces, apple producing area, 2005

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having a significant disease problem. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.3 Weed incidences and management practices

To manage weeds, apple growers reported mulching as the most common practice used on 27.1% of the producing area. By far the most common "other" method was mowing, which was used on 17.8% of the producing area (Figure 20).

Figure 20 Practices for weed management, selected provinces, apple producing area, 2005

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.3.1 Changes in weed incidences

Growers were asked if, in 2005, weeds were more, less or about equally prevalent compared to the last five years. Seventy-nine percent of the producing area was operated by growers who reported that the incidence of weeds was "about the same" in 2005 compared to the last five years (Figure 21).

"Much less or less" weed pressure was indicated for 12.5% of the producing area and the incidence of weeds was "more or much more" on 8.5% of the producing area. Ontario had the most growers reporting higher weed incidence than in the past (15.3% of the producing area).

Figure 21 Incidences of weeds compared to the last five years, selected provinces, apple producing area, 2005

Note: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. Source: Statistics Canada, 2005 Crop Protection Survey.

3.6.3.2 Responses to higher weed pressure

Growers facing "more or much more" weed problems were asked what they planned to do to reduce weed problems during the next growing season. Less than 42% of the producing area with higher weed pressure was operated by growers who planned to switch to different herbicides in the future. About 29.3% of the producing area with higher weed pressure area was operated by growers who plan to switch to a different weed control practice (Figure 22).

Notes: Includes Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. For farms that reported having "more" or "much more" weed problems compared to the last five years. Source: Statistics Canada, 2005 Crop Protection Survey.

[■] Much less or less □ About the same ■ More or much more

3.7 Management practices and pest resistance to pesticides

3.7.1 Practices used to manage resistance to pesticides

Growers were given a list of four practices that can help manage the emergence of populations of weeds, insects and diseases resistant to pesticides and were asked to identify which practices they commonly use that can help avoid the emergence of pest resistance. Two practices involve rotation between different pesticide classes (different modes of action) and two are basic preventive IPM practices (planting a resistant variety and reducing pest populations through non-chemical means).

Growers operating 86.7% of the apple producing area said that they either always rotated or sometimes rotated to pesticides in different chemical families (Figure 23).

Reducing pest populations through non-chemical means was used on 37.6% of the producing area, while selecting more pest resistant crop varieties was reported on less than 4% of the producing area.

Figure 23 Practices used to prevent pest resistance to chemical products, selected provinces, apple producing area, 2005

3.7.2 Growers' perception of pests becoming resistant to pesticides

Respondents were asked if any weeds, insects or plant diseases on their entire operation had displayed signs of resistance to the pesticide applied to control them. Growers were then asked to what extent pests are becoming resistant to each group of pesticides. Figure 24 displays the reported degree of resistance for weeds, insects and plant diseases.

Growers reported that weeds are not resistant to herbicides on 47.1% of the apple producing area, while weeds are becoming slightly resistant on more than one-third (37.1%) of the apple producing area. About 7.4% of the producing area was plagued by weeds reported to be resistant or very resistant, while resistance status was unknown on 8.4% of the area.

The prevalence of resistance was similar among insects, where growers reported no signs of resistance in insects on 45.4% of the producing area and slight resistance on 33.0% of the producing area. Insects were regarded as resistant or very resistant on 15.7% of the area.

Disease pathogens were reported as not resistant on 53.1% of the producing area, slightly resistant on 30.4% and as resistant or highly resistant on 10.9% of the producing area.

Canadian apple producers face a significant challenge in managing resistance, given that resistant weeds, insects and plant diseases are already present on about one-third of the producing area.

Figure 24 Growers' perception that pests are becoming resistant to pesticides, selected provinces, apple producing area, 2005

■ Resistant to very resistant ■ Slightly resistant □ Not resistant ■ Don't know

4 Conclusion

.

Canadian apple growers cope with threats to their crops from insects, diseases and weeds. To control these threats, growers use an integrated approach to control pests, which includes the use of pesticides and best management practices, allowing them to produce the quality crop consumers want to buy. Because apples are a perennial crop, with the same apple trees producing apples for many years, growers need to make decisions on what trees to plant in light of the long-term impact that variety selection has on both the production and marketing of fruit.

The use of pesticides is regulated in Canada through the Pest Control Products Act. Pesticides are evaluated for their safety in terms of the environment and human health. Pesticides used in Canada are considered to be safe if used according to the instructions provided on the label.

The data from this survey show that apple growers are using integrated pest management (IPM) practices to help control insects, diseases and weeds. Integrated pest management involves the use of a system of tools that work together to control pests. Tools include pesticides, but they also include a host of cultural practices and non-chemical tools that can help to control disease.

Appendix B Questionnaire
STEP 2: Questions about the orchards where APPLES were grown for sale in 2005.
2 What UNIT OF MEASURE will be used to report land areas? ²² This same unit should be used throughout the questionnaire.
(Check one circle only.) O ⁰¹ Acres O ⁰² Hectares O ⁰³ Arpents (Quebec only)
3 What was your total producing and non-producing apple area (all varieties) on this operation in 2005?
4 What was your total producing apple area (all variaties)?
5 How many orchards (varieties of apple, cultivars or plots) produced apples for sale?
Include:
 all areas of apples grown for sale at roadside stands, farmer's markets or U-pick systems.
Do not include:
► apples grown for home use.
To save time, this interview will focus on one producing orchard only. First, we will list all producing orchards (varieties of
apple, cultivars or plots) in production in 2005. You can use your identification system (name, number or description) to report each orchard. Then, I will select one producing orchard (variety of apple, cultivar or plot) from the list.
6 What were your producing orchards in 2005?
If the respondent uses a different term than "orchard" (variety of apple, cultivar or plot) to describe the apple producing area, 25
please specify here:
In there are more than 10 producing orchards, list the 10 largest producing orchards.
Name, number or orchard description Name, number or orcha d description
3 8
Now, I will select one producing orchard from all producing orchards in 20. 5.
Interviewer action: enter the selected orchard (v. riety of apple, cultivar or plot) number
The selected producing orchard is: During this interview, I will ask you questions about this orchard.
7 What was the area of this selected orchard (variety of a cultivar or plot)?
8 How many bearing trees were in this selected c ·charo?
9 What year was the selected orchard planted ?
10 in 2005
a) which apple veriety (or cultiver was grown?
b) when did harvest star, 2
c) when did har event finite in the finite interval $D D M M^{33}$ $D D M M^{36}$ $D D M M^{39}$ $D D M M^{42}$
STEP 3: Questions about herbicide, insecticide or fungicide applications from January 1 to December 31, 2005 on
the orchard selected in Step 2.
11 In 2005, did you apply any herbicides, insecticides, fungicides or other pesticides on the selected orchard?
⁰¹ \bigcirc Yes ⁰² \bigcirc No If "YES", continue to question 12, If "NO" \rightarrow Go to Step 4.
12 What format was used to keep records of herbicides insecticides fundicides or other pesticides applied to this orchard?
Was it? (Check all that apply.)
⁰¹ O Written ⁰² O Electronic/computer file ⁰³ O No record kent
12 What information in least in your large/second leasting system?
is what mornation is kept in your logs/record-keeping system?
Does it include the? (Check all that apply.)
Does it include the? (Check all that apply.) ⁴⁵ O Date of application ⁴⁸ O Product applied ⁵¹ O Temperature at application
Does it include the? (Check all that apply.) 45 O Date of application 48 O Product applied 51 O Temperature at application 46 O Identification of orchard 49 O Rate of application 52 O Targeted weed, insect or disease
45 0 Date of application 48 0 Product applied 51 0 Temperature at application 46 0 Identification of orchard 49 0 Rate of application 52 0 Targeted weed, insect or disease 47 0 Total area treated 50 0 Wind speed 53 0 Other, specify:
Does it include the? (Check all that apply.) 45 O Date of application 48 O Product applied 51 O Temperature at application 45 O Identification of orchard 49 O Rate of application 52 O Targeted weed, insect or disease 47 O Total area treated 50 O Wind speed 53 O Other, specify: 54 14 Did the company or person purchasing your produce require the use of specific herbicides, insecticides or fungicides as 55
Does it include the? (Check all that apply.) 45 O Date of application 48 O Product applied 51 O Temperature at application 46 O Identification of orchard 49 O Rate of application 52 O Targeted weed, insect or disease 47 O Total area treated 50 O Wind speed 53 O Other, specify:

Appendix B Questionnaire
STEP 4: Questions about WEED, INSECT, DISEASE AND OTHER PEST MANAGEMENT PRACTICES in 2005 for the orchard selected in Step 2
16 Which practices do you use in your spray operation in this orchard in 2005?
 ⁸¹⁷ O Use the highest labelled water volume ⁸²³ O Spray only when wind blows away from sensitive areas
⁸¹⁸ O Replace nozzles at least every three years ⁸²⁴ O Maintain lower pressure or use low-drift nozzle
⁸¹⁹ O Maintain sprayer travel speed less than 16 km/h ⁸²⁵ O Use protective shrouds or cones around sprayer boom
820 O Maintain low boom height 826 O Other, specify: 827
821 O Adjust airblast direction for target height
17 In 2005, for the selected orchard, was the incidence of <u>INSECTS</u> compared to the last five years? ⁸⁴⁴
(Check one circle only.) ⁰¹ O Much less ⁰² O Less ⁰³ O About the same
If the answer is "More" or "Much more", continue to question 18. Otherwise \rightarrow Go to Question 19.
18 What do you plan to do during the next growing season to reduce your INSECT problems?
Will you? (Check all that apply)
951 O Scout for insect or damage presence 849 O Take actions to disrupt insect reproduction or development
302 O Use forecasting systems 850 O Increase rate of insecticide applications 847 O Puth the different insecticide 851 O Out
848 O Apply an additional insecticide 0 Other, specify: 853
19 In 2005 did you doal with any NEW INSECTS in this field?
b If you what was the main insect?
20 In 2005, for the selected orchard, what was the MOST PREVALENT INSECT you had to control?
If there was no significant insect problem, enter "0" and skip to Question 22.
21 What did you do to control the <u>MOST PREVALENT INSECT</u> ?
 O Apply insecticides throughout the growing season O Time insecticide applications to target the insect at diverget to velopment stages
What were the developmental stagrs? ^{A59} O Early nymph or egg stages
If not applicable, go to next choice: Box 562 O Larval or nymphal stages
861 O Adult
 O Take other steps to disrupt the reproductio. If this insect ⁸⁶³ O Take other actions to disrupt the non-hological development of this insect
 ⁸⁶⁵ O Release beneficial organisms to on, of this insect
866 O Manage this orchard and its surrou iding area to attract beneficial organisms
22 In 2005, for the selected orchard, was the incidence of DISEASES (fungus, bacteria, mildew) compared to the last five years?
(Check one circle only.) ⁰¹ O Nucr was ⁰² O Less ⁰³ O About the same
⁰⁴ O More ⁰⁵ O Much more
If the answer is "More" or "Much more", continue to question 23. Otherwise \rightarrow Go to Question 24.
23 What do you plan to do Jurin, the next growing season to reduce your <u>DISEASE</u> problems?
Will you? (Check a that apply)
953 O Scout full disease damages 954 O Use forecasting systems 869 O Iscarse at a function of function of function of the set
870 O Switch to a different fungicide 874 O Other, specify: 875
871 O Apply an additional fungicide 876
24 In 2005, did you deal with any <u>NEW DISEASES</u> in this orchard?
⁰² O No ⁰¹ O Yes
► If yes, what was the main disease?
25 For the selected orchard, what was the MOST PREVALENT DISEASE (fungus, bacteria, mildew) you had to control?
If there was no significant insect problem, enter "0" and skip to Question 28.
26 What tools/methods did you or your advisor use to make decisions on when to apply fungicides in this orchard to control the MOST PREVALENT DISEASE?
880 O A set application schedule (calendar spraving)
Was the decision based on? ⁸⁸¹ O Scouting reports and thresholds
(Check all that apply.) 882 O Regional forecasting/warning services
 O Climatic conditions (degree days, moisture) Anticipation of the state of the stat
 O Advice from other operators 885 O Advice from a chemical salesperson

Appendix B Questionnaire	
STEP 7: Questions about the characteristics of the operator(s) and agricultural operation as of December 31, 2005.	
36 Which of the following best describes this farm operation? 918 (Check one circle only.)	
(If the operation is a family or hobby farm, check 1, 2 or 3). 01 O Sole proprietorship 01 O Sole proprietorship O 02 O Corporation (Limited company) 03 O Partnership	
 ⁰⁴ O Cooperative or communal operation (e.g., Hutterite colony) ⁰⁵ O Other, specify:	91
37 Are you the person who looked after the day-to-day crop management decisions on this operation? 918 Yes O 01 No O 02	
38 How many operators (decision-makers) 18 years of age and over were responsible for this operation?	919
39 What was the age of:	
¹ Operator 1?	920
² Operator 2 (minimum age 18)?	921
40 What is the highest level of education completed by the operator(s)?	23
If there was only one operator, enter the level of education in the box for the Operator 1. Operator 1. Operator 1	<u>or 2</u>
¹ Some elementary or secondary (high) school (include upgraded and special education)) ⁰¹
² Completed secondary (high) school (graduation certificate or equivalent)) 02
³ Some post-secondary, including some college or university courses) 03
⁴ Completed college or university certificate or diploma below bachelor level (e 1, trao , technical or vocational school, agricultural diploma, business or community college, CEGEP)) 04
⁵ Completed university degree program (include bachelor's degree and above)) 05
41 How many years has the most experienced operator on this farm na paged a farm business?	924
R	
STEP 8: Agreement to share data	
	_
Thank you for taking the time to particl, ate in our survey. In order to avoid duplication, Statistics Canada has entered into a data sharing agreement under Section 12 of the Statis, is Act with the three federal government departments listed below to share the responses from this survey. The agreement is that no names or addresses or any other identifier be shared with these departments and that the information be kept confidential and used only for statistical and research purposes by these three departments.	
42 Do you agree to share this information with:	
a) Agriculture and Agri-Food Canada?	92
c) Environment Canada? Yes 0 ⁰¹ No 0 ⁰²	92
In order to extend the research capabilities of this survey, Statistics Canada intends to combine the information from this survey with the 2005 Fruit and Vegetables Survey information that Statistics Canada obtained from your operation.	
43 Do you agree that Statistics Canada combines information from this survey with the information you provided on the 2005 Fruit and Vegetables Survey?	92
44 Would you like to receive a summary report of the survey results? Yes 0 ⁰¹ No 0 ⁰²	93
If "YES" continue to Question 45. If "NO" \rightarrow Go to Step 9	
45 What is your e-mail (or mailing) address? Your address will <u>NOT</u> be shared with any other government department.	
Enter "MAIL" if the respondent prefers to receive the report by mail.	
E-mail address	93
