Highlights

- In 2012, 45% of Inuit aged 15 and older reported excellent or very good health; the comparable figure for the total population of Canada was 63%.

- In 2012, an estimated 43% of Inuit had been diagnosed with a chronic condition by a health professional.

- The chronic conditions most commonly reported by Inuit were high blood pressure (12%), arthritis (12%), asthma (7%), mood disorders (7%), and diabetes (5%).

- Just over half (52%) of Inuit aged 15 and older reported that they smoked cigarettes daily, compared with 16% of Canadians overall.

- While 33% of Inuit reported that they had not consumed alcohol in the past 12 months, 26% reported heavy drinking, that is, five or more drinks on a single occasion at least once a month.

- In the previous year, 59% of Inuit aged 15 and older had seen or talked to a medical doctor and 49% had consulted a nurse.

- An estimated 14% of Inuit reported needing health care in the past year, but not receiving it. The most common reason for not receiving this care was that it was not available in the area.

- Four in ten (41%) Inuit aged 15 and older lived in households that experienced food insecurity, compared with 8% of the total population of Canada. Furthermore, 22% reported that in the previous 12 months they had personally experienced hunger because they could not afford to buy enough food.

- In 2011, 25% of Inuit lived in households with more than one person per room, and 29% were in dwellings that needed major repairs; the corresponding figures for Canada overall were 3% and 7%, respectively.
About this study

Unless otherwise indicated, the data pertain to the Inuit population aged 15 and older. Data are presented for the total Inuit population, for those living in Inuit Nunangat (the Inuit homeland) and its four component regions, and for Inuit living outside Inuit Nunangat. The analysis in this report is based on a sample of 3,668 Inuit. Reported differences between Inuit living inside and outside Inuit Nunangat are statistically significant (p > 0.05). Direct comparisons are not made between the Inuit regions; however, 95% confidence intervals are shown in all charts. Where available and appropriate, comparable data are presented for the total population of Canada, and all differences are statistically significant unless otherwise stated.

Two estimates were considered to be significantly different from one another if their 95% confidence intervals did not overlap. This is a conservative approach, because statistical tests of significance can detect differences even when confidence intervals overlap. However, when comparing results from two different surveys, such as the 2012 APS and the 2012 Canadian Community Health Survey or the 2001 APS and 2012 APS, this approach is not considered conservative.

Responses of don’t know, refusal, and not stated were excluded from the denominators in the calculation of estimates for 2012 and 2001.

Differences between the 2001 and 2012 Aboriginal Peoples Surveys are statistically significant unless otherwise stated. Readers should note that the two surveys used different methodologies. In addition, the 2001 survey did not include the community of Hopedale, Newfoundland and Labrador (Nunatsiavut). More information is available in the Aboriginal Peoples Survey, 2012: Concepts and Methods Guide and the 2001 APS Concepts and Methods Guide.

Estimates with coefficients of variation greater than 16.6% but less than or equal to 33.3% should be interpreted with caution; these are noted (E) throughout the report. Estimates with coefficients of variation greater than 33.3% were suppressed.

Sampling weights were applied to all analyses to account for the sample design, non-response and known population totals. A bootstrapping technique was used when calculating estimates of variance.

Introduction

This paper provides basic health indicators for the Inuit population, as well as selected social determinants of health, based on results of the Aboriginal Peoples Survey 2012–Education and Employment. Topics covered include health status, chronic conditions, health behaviours, obesity, access to health care, food insecurity, housing, and culture and language.

Inuit population

Inuit are the original inhabitants of the Arctic, where they have lived for thousands of years and where they have developed a unique culture with distinct beliefs and practices (Inuit Tapiriit Kanatami, 2014a).

The four regions of Inuit Nunangat

According to the National Household Survey, the Inuit population of Canada totalled just under 60,000 in 2011 (Table 1), an increase of 18% from 2006. Nearly three-quarters (73%) of Inuit lived in Inuit Nunangat, which is comprised of four regions: Nunatsiavut (Labrador); Nunavik (northern Quebec); Nunavut; and the Inuvialuit region (Northwest Territories).  

---

1. Inuit of the Western Arctic are known as “Inuvialuit.” In this report, the term “Inuit” includes Inuvialuit.
The Inuit population is young, with a median age of 23 years in 2011 versus 40 years for Canadians overall. The median age of Inuit in Inuit Nunangat was slightly younger, at 22 years; those living outside Inuit Nunangat were older, with a median age of 26 years.²

Median Age (years) 23 22 29 21 21 26 26

Compared with the population of Canada overall, Inuit face challenges in terms of physical and mental health and well-being (Gionet and Roshanafshar, 2013; Garner, Carrière, and Sanmartin, 2010).³ Evidence of this health gap includes shorter life expectancy (Peters, 2013; Gionet and Roshanafshar, 2013) and higher infant mortality rates (Zhong-Cheng, Senécal, Simonet, Guimond, Penney and Wilkins, 2010).

According to the World Health Organization, health is strongly influenced by “the conditions in which people are born, grow, live, work and age, including the health system” (World Health Organization, 2013). It is not within the scope of this report to present all the social, economic, cultural and environmental conditions that are relevant for Inuit health, but a number of them are of specific concern, namely, health care access (Health Council of Canada, 2012; Archibald and Grey, 2000; O’Neil, Koolage, and Kaufert, 1988), food security (Chan, Fedliuk, Hamilton, Rostas, Caughey, Khnlein, Egeland and Loring, 2006; Lambden, Receveur, Marshall and Kuhnlein, 2006; Willows, 2005), housing (Tait, 2008; Young and Mollins, 1996), and culture and language (Loppie Reading and Wien, 2009; Richmond, Ross and Egeland, 2007; Kirmayer, Brass & Tait, 2000). Furthermore, income is generally regarded as the key social determinant of health (Tjepkema, Wilkins, Long, 2013; Commission on Social Determinants of Health, 2008; Auger, Raynault, Lessard and Choinière, 2004).

² Data for Inuit outside of Inuit Nunangat, as it represents less than 1% of the Canadian population, should be used with caution because of lower reliability. For additional information, please refer to the Aboriginal Peoples Reference Guide, National Household Survey, 2011.

³ The World Health Organization defines health as a state of complete physical, mental and social well-being, not merely the absence of disease or infirmity. World Health Organization, 2013.
Health outcomes

Excellent or very good self-reported health
Self-reported health is a general measure of well-being that has been proven to be a reliable indicator of health across cultures and socio-economic circumstances (Burström, and Fredlund 2001; DeSalvo, Bloser, Reynolds, He and Muntner, 2005; Rohrer, Arif, Denison, Young and Adamson, 2007). According to the 2012 Aboriginal Peoples Survey (APS), 45% of Inuit reported excellent or very good health (Chart 1) while the comparable figure for the total population of Canada was 63% (Canadian Community Health Survey, 2012). A further 38% of Inuit reported good health, and 18%, fair or poor health. Between 2001 and 2012, the percentage of Inuit who reported excellent or very good health fell from 56% to 45%.

Chart 1
Percentage reporting excellent or very good health, by Inuit region, Inuit population aged 15 and older, 2012

Note: The lines overlaid on the bars in this chart indicate the 95% confidence interval. They enable comparison of statistical differences between estimates.

In 2012, Inuit living in Inuit Nunangat were less likely to report excellent or very good health (40%) than were those who did not live in Inuit Nunangat (56%).

---

The prevalence of self-reported excellent or very good health tends to decline with advancing age. Whereas 54% of 15- to 19-year-old Inuit in Inuit Nunangat reported excellent or very good health, the percentage was 21% among those aged 55 and older (Chart 2). Outside Inuit Nunangat, more than two-thirds of Inuit in the 15-to-34 age range reported excellent or very good health, compared with 36% of those aged 55 and older.

**Chronic conditions**

The APS defined a “chronic condition” as a long-term condition that is expected to last or has already lasted at least six months, and that was diagnosed by a health professional. In 2012, 43% of Inuit (47% of women and 39% of men) reported at least one chronic condition. Half of them had just one condition; 26% had two conditions; and the remaining 25%, three or more.

About a third (37%) of Inuit in Inuit Nunangat reported having been diagnosed with a chronic condition, compared with more than half (56%) of those living outside Inuit Nunangat (Chart 3). These results must be interpreted cautiously. Reporting a chronic condition is contingent on having seen or talked to a health care professional. Because of limited access to health care providers in Inuit Nunangat (Gionet and Roshanafshar, 2013), the number of chronic conditions “diagnosed” and the number actually experienced by the Inuit may differ (see Access to Health Care, below). As well, some Inuit with serious conditions may leave Inuit Nunangat to obtain better access to medical care (Tjepkema, 2010; Institute of Urban Studies, 2004).

---

5. Because of changes to the chronic conditions content, the overall chronic conditions indicator is not comparable between the 2001 and 2012 Aboriginal Peoples Surveys.
The likelihood of reporting a chronic condition rose with age from 32% of Inuit aged 15 to 24 to 68% of those aged 55 and older. As well, older Inuit were more likely than younger Inuit to report multiple chronic conditions. At age 55 and older, 38% of Inuit who had been diagnosed with at least one chronic condition reported three or more chronic conditions; at ages 15 to 24, the figure was 15%.6

**Most prevalent conditions**

The chronic conditions most commonly reported by Inuit were high blood pressure (12%), arthritis (12%), asthma (7%), and mood disorders (7%), such as depression or bipolar disorder (Table 2). Diabetes (excluding gestational diabetes) was reported by 5%. The vast majority (97%) of all cases of diabetes (including gestational diabetes) were Type 2 diabetes.

---

6. The estimates for Inuit aged 15 to 24 and 25 to 54 who reported that they had been diagnosed with three or more chronic condition are not significantly different.

7e use with caution

Note: When the rates of selected chronic conditions for the total population of Canada are compared to the Inuit population, it is necessary to age-standardize the Canadian population to reflect the younger age structure of the Inuit population.

Health behaviours

Smoking cigarettes
The health risks of smoking are well established and include heart disease, oral and lung cancer, emphysema and bronchitis (Health Canada, 2013). In 2012, 16% of the total population of Canada aged 15 and older were daily smokers (Canadian Community Health Survey, 2012). According to the 2012 APS, half (52%) of Inuit aged 15 and older smoked cigarettes daily, and another 9% were occasional smokers (Chart 4).7 The percentages of Inuit men and women who smoked daily, occasionally or not at all did not differ significantly.

7. The APS question was “At the present time, do you smoke cigarettes daily, occasionally or not at all?”
Chart 4
Prevalence of daily cigarette smoking, by Inuit region, Inuit population aged 15 and older, 2012

</tr>
</tbody>
</table>

Note: The lines overlaid on the bars in this chart indicate the 95% confidence interval. They enable comparison of statistical differences between estimates.

Among Inuit in Inuit Nunangat, 63% were daily smokers (Chart 4), and another 10% were occasional smokers. Of the four regions, only Nunatsiavut’s rate of daily smoking (50%) was below that of Inuit Nunangat overall.\(^8\) Daily smoking was less prevalent among Inuit living outside Inuit Nunangat—29% were daily smokers, and 8%\(^E\) were occasional smokers.

Between 2001 and 2012, the prevalence of daily smoking among Inuit overall dropped from 61% to 52%. However, in Inuit Nunangat, the percentage who smoked cigarettes daily in 2012 (63%) was not significantly different from 2001 (66%).

Alcohol consumption
A third of Inuit (36% of women and 29% of men) had not consumed alcohol in the past 12 months. This was not significantly different from 2001. Between 2001 and 2012, the percentage of Inuit who had not consumed alcohol in the past 12 months fell from 41% to 33%.

Inuit living in Inuit Nunangat were more likely than were those living outside Inuit Nunangat to report non-consumption of alcohol: 40% versus 17%. The percentages who had not consumed alcohol in the previous 12 months were below the estimate for Inuit Nunangat as a whole in Nunavik (31%), the Inuvialuit region (31%) and Nunatsiavut (28%). In Nunavut, where a number of communities restrict or prohibit the sale and/or possession of alcohol (Wood, 2010), 46% of Inuit reported that they had not consumed alcohol in the past 12 months.

\(^{8}\) The estimate for the Inuvialuit region is lower than that of Inuit Nunangat, but the difference is not statistically significant.
Heavy drinking\(^9\)—five or more drinks on a single occasion at least once a month (Statistics Canada, 2013)—has been linked to health and social problems, including cancer, liver cirrhosis, Fetal Alcohol Spectrum Disorder, motor vehicle accidents, alcohol poisoning, family disruption, crime and violence (Health Canada, 2013). About a quarter (26%) of Inuit aged 15 and older reported heavy drinking—30% of men and 23% of women. In 2012, 18% of the total population of Canada aged 15 and older reported heavy drinking (Canadian Community Health Survey, 2012). In 2001, 26% of Inuit had reported heavy drinking, a percentage not significantly different from 2012.

Heavy drinking was equally prevalent in and outside Inuit Nunangat: 26% and 25%, respectively. The prevalence of heavy drinking varied by region: 47% in Nunatsiavut, 38% in the Inuvialuit region, and 34% in Nunavik, all of which were significantly higher than the estimate for Inuit Nunangat overall. Heavy drinking was reported by 20% of Inuit in Nunavut, significantly below the estimate for Inuit Nunangat overall.

**Prevalence of obesity**

Links between obesity and chronic conditions such as type 2 diabetes, hypertension, cardiovascular disease, gallbladder disease and certain types of cancer have been well established (Navaneelan and Janz, 2014).

---

9. Heavy drinking was determined using question ALC_03, which asked “How often in the past 12 months have you had five or more drinks on one occasion?” Response categories were Never, Less than once a month, Once a month, 2 to 3 times a month, Once a week, More than once a week.
The APS found that 30% of Inuit aged 18 and over were overweight and 26% were obese, according to their Body Mass Index (BMI), which was calculated using self-reported height and weight.\textsuperscript{10} Four in ten Inuit aged 18 and over, 42%, were within the category of “normal weight” and 3% were considered underweight. However, it should be noted that there is debate regarding whether standard BMI cut-off points are appropriate for the Inuit population (Charbonneau-Roberts, Saudny-Unterberger, Kuhnlein and Egeland, 2005; Young, Bjerregaard, Dewailly, Risica, Jorgensen and Ebbersson, 2007; Lear, Humphries, Frohlich and Birmingham, 2007).

Among Inuit aged 18 and over living within Inuit Nunangat, 28% of Inuit were overweight and 24% were obese while outside Inuit Nunangat, 32% were overweight and 31% were obese. The differences between Inuit living inside and outside Inuit Nunangat were not statistically significant.

Social determinants of health

According to Inuit Tapiriit Kanatami (2014b), a number of social determinants of health are particularly important for Inuit. Those most obviously associated with health outcomes are health care access, which pertains to the maintenance of health and treatment of illness, as well as food insecurity and housing, which are directly linked to income, a critical determinant of health for most populations (Raphael, 2009). For Inuit in particular, language, social support, and traditional activities are related to health through cultural continuity (Inuit Tapiriit Kanatami, 2014b).

Access to health care

Access to health care is often limited in Inuit communities, many of which are served by a health centre staffed by a nurse or nurse practitioner.\textsuperscript{11} Moreover, recruitment, retention and training of health personnel are often issues that further hinder access to primary care (Health Council of Canada, 2012). To receive advanced diagnosis and treatment, many Inuit must leave their communities, sometimes for extended periods (Tjepkema, 2010; Institute of Urban Studies, 2004).

Contact with health professionals

Three-quarters (75%) of Inuit had seen or talked to at least one health professional (excluding dental professionals) in the year before their APS interview (Table 3). A larger percentage of women than men had consulted a health professional: 80% versus 68%. Inuit in Inuit Nunangat were less likely to have contacted a health professional in the past year than were those living outside Inuit Nunangat: 70% versus 84%.

Type of health professionals contacted

In the previous year, 59% of Inuit had seen or talked to a medical doctor, and 49% had seen or talked to a nurse (Table 3).\textsuperscript{12} By comparison, 79% of all Canadians had consulted a medical doctor, and 12% had consulted a nurse (Canadian Community Health Survey, 2012).

\textsuperscript{10} Research demonstrates that self-reported height and weight results in an underestimation of obesity, as respondents tend to overestimate height and underestimate weight (Navaneelan and Janz, 2014; Connor Gorber, Shields, Tremblay and McDowell, 2008).

\textsuperscript{11} Nurse practitioners are registered nurses who have additional education and nursing experience (Canadian Nurses Association, 2014).

\textsuperscript{12} Medical doctor includes family doctors, general practitioners and pediatricians, and specialists such as surgeons, allergists, orthopedists and psychiatrists.
Between 2001 and 2012, the percentage of Inuit who had consulted a doctor rose from 50% to 59%; the percentage who had consulted a nurse in 2012 did not differ significantly from 2001.

Inuit in Inuit Nunangat were less likely than those living outside Inuit Nunangat to have seen or talked to a doctor (49% versus 82%), but more likely to have seen or talked to a nurse. In fact, the percentage of Inuit in Inuit Nunangat who had contacted a nurse (58%) exceeded the percentage who had contacted a doctor (49%).

.. not available for a specific reference period

Note: The CCHS contains a more exhaustive list of health care professionals than the APS. As such, the indicator of ‘At least one health care professional’ is not comparable across surveys.

**Regular medical doctor**

In 2012, 39% of Inuit aged 15 and older (45% of women and 32% of men) had a regular medical doctor (family doctor, pediatrician or general practitioner); the corresponding figure for the total Canadian population aged 15 and older was 85% (Canadian Community Health Survey, 2012).

Fewer than a quarter (23%) of Inuit in Inuit Nunangat had a regular doctor, compared with 74% of those living outside Inuit Nunangat. The percentages varied by region from 19% in Nunatsiavut, Nunavut and the Inuvialuit region to 37% in Nunavik.

When Inuit who did not have a regular doctor were asked the reason, 65% of those in Inuit Nunangat reported that no doctors were available in the area; outside Inuit Nunangat, this reason was cited by 15%.

**Unmet health care needs**

According to the 2012 APS, in the previous year, 14% of Inuit experienced a time when they felt they needed health care but did not receive it; this compared with 10% of the total population of Canada.
In Inuit Nunangat, 14% of Inuit did not receive health care when it was needed; outside Inuit Nunangat, the corresponding figure was 16%, a difference that was not significant. Unmet health care needs were reported by 9% in Nunavik, a percentage lower than the estimate for Inuit Nunangat as a whole; for the other regions, the percentages did not differ significantly from the estimate for Inuit Nunangat as a whole.

Among Inuit who did not receive care, the most common reasons were that it was not available in the area (25%), and that it was not available at the time required (15%).

**Source:** Aboriginal Peoples Survey, 2012.

**Contact with dental professionals**

Inuit have limited access to dental care, a situation that has serious consequences for Inuit oral health (*Inuit Oral Health Survey Report 2008-2009*, 2011). Typically, communities are served by visiting dental professionals (dentists and hygienists) who have time to see only the most serious cases.

According to the 2012 APS, 56% of Inuit had seen a dental professional in the past year (Chart 7). Another 23% had seen a dental professional between one and three years earlier, and for 20%, their last contact had been more than three years earlier (or never).

In Inuit Nunangat, 50% of Inuit had seen a dental professional in the past year, compared with 69% of those living outside Inuit Nunangat.13

---

13. Data from 2001 are not directly comparable to 2012, as the 2001 question asked if the respondent had seen or talked to a dentist or orthodontist, while the 2012 question asked if the respondent had seen a dental professional.
Food insecurity

Food security is “when all people, at all times, have physical and economic access to sufficient, safe, and nutritious food to meet their dietary needs and food preferences for an active and healthy life (Food and Agricultural Organization, 1996).” The absence of food security (food insecurity) is a contributing factor to poor health, as it is associated with restricted mobility, multiple chronic conditions, and experiencing major depression and distress (Tarasuk, 2009). Moreover, food insecurity is a well-documented problem among Inuit (Rosol, Huet, Wood, Lennie, Osborne and Egeland, 2011). According to the Northern Food Basket, it costs $360 to $450 a week to provide healthy diet to a family of four living in northern regions, whereas the same basket of goods would cost $200 to $250 in southern Canada (Aboriginal Affairs and Northern Development Canada, 2014).

Food insecurity refers to situations, when, for example, the food that was purchased does not last, and there is not enough money to buy more; a household cannot afford to eat balanced meals; or household members cut the size of their meals or skip meals because there is not enough money for food.

In 2012, 41% of Inuit aged 15 and older lived in households that experienced food insecurity in the past 12 months (Chart 8).14,15 This compared with 8% of the total population of Canada.

---

14. The APS collected information on household food insecurity through a series of questions focused on availability of food and the ability to purchase food. Information was not collected on the sharing of country food or initiatives such as community freezers.
15. Data on food insecurity were not collected in 2006 or 2001.
More than half (53%) of Inuit in Inuit Nunangat lived in households that experienced food insecurity, compared with 17% of those outside Inuit Nunangat. The prevalence of food insecurity varied by region: 56% in Nunavut, 55% in Nunavik, 45% in Nunatsiavut and 32% in the Inuvialuit region.

One in five (22%) Inuit reported that in the previous 12 months they had personally been hungry because they could not afford enough food (Chart 8). The figure was 27% for Inuit in Inuit Nunangat, compared with 13% for those living outside Inuit Nunangat.

### Housing

Poor housing conditions have been linked to health problems such as the spread of infectious diseases and respiratory tract infections in infants, and to social problems such as violence and low achievement in school (Inuit Tapiriit Kanatami, 2007).

More than one person per room is a measure of “crowding.” The 2011 National Household Survey found that 25% of Inuit lived in households with more than one person per room (Chart 9), compared with 3% of the total population of Canada. Nonetheless, the percentage of Inuit in homes with more than one person per room was down from 29% in 2001.

In Inuit Nunangat, 33% of Inuit lived in houses with more than one person per room in 2011; among Inuit outside Inuit Nunangat, the figure was 5%. Percentages were highest in Nunavik (43%) and Nunavut (34%); percentages were lower in the Inuvialuit region (15%) and Nunatsiavut (13%), but still more than double the estimate for Inuit living outside Inuit Nunangat.

---

16. Other measures include the National Occupancy Standard (NOS), developed by the Canadian Mortgage and Housing Corporation, to determine if a dwelling has enough bedrooms for the size and composition of the household (Statistics Canada, 2014).
17. Data from the National Household Survey (NHS) rather than the Aboriginal Peoples Survey are used because of reduced sampling variability in the NHS.
In 2011, 29% of Inuit, compared with 7% of the total population of Canada (Chart 9), lived in dwellings that needed major repairs to, for example, correct defective wiring or plumbing or structural problems with walls, floors and ceilings. The percentage of Inuit living in homes needing major repairs was higher in 2011 than in 2001 (22%).

More than a third (35%) of Inuit in Inuit Nunangat lived in dwellings that needed major repairs, compared with 15% of those outside Inuit Nunangat. The percentage of Inuit in dwellings needing major repairs ranged from 30% in the Inuvialuit region to 39% in Nunavik.

**Culture and language**

Inuit health and well-being are strongly tied to culture (Inuit Tapiriit Kanatami, 2014b; Loppie Reading and Wien, 2009; Richmond, Ross and Egeland, 2007). The 2012 APS collected information on a number of aspects of culture including language use, community ties, and traditional activities such as hunting, fishing, trapping and gathering wild plants.

**Language**

In 2012, 55% of Inuit reported that they could speak an Inuit language very well or relatively well, down from 65% in 2001 (Chart 10). The figure was 75% among Inuit living in Inuit Nunangat, compared with 10% among those outside Inuit Nunangat. The percentages who could speak an Inuit language very well or relatively well ranged from 18% in the Inuvialuit region to 96% in Nunavik.

In most regions, Inuit aged 55 and older were more likely than those aged 15 to 24 to report the ability to speak an Inuit language very well or relatively well: 95% versus 64% in Nunavut; 51% versus 9% in Nunatsiavut, and 43% versus 11% in the Inuvialuit region. In Nunavik, the percentages were nearly identical at 96% and 95%.
Family and community

Family and community are central components of Inuit identity and culture (Inuit Tapiriit Kanatami, 2014a). As well, social support and connectedness can contribute to better health outcomes (Richmond, Ross and Egeland, 2007; Chief Public Health Officer, 2008).

Two-thirds of Inuit, 66%, rated their ties with family members in other households as very strong or strong (Chart 11). The percentage reporting very strong or strong ties among family members was higher in Inuit Nunangat (70%) than outside Inuit Nunangat (57%).

Two-thirds (66%) of Inuit reported that in a time of need they would turn only to family members for support; 22% reported they would turn to both family and non-relatives. Fewer than 10% of Inuit would turn only to non-relatives, and 5% reported that they had no one to whom they could turn.\(^\text{18}\)

\(^{18}\) Differences between Inuit Nunangat and outside Inuit Nunangat are not statistically significant.
Hunting, fishing, trapping or gathering
According to the APS, 74% of Inuit (81% of men and 68% of women) had hunted, fished, trapped or gathered wild plants in the 12 months before their interview (Chart 12). Fully 82% of Inuit living in Inuit Nunangat had engaged in these activities, compared with 55% of those outside Inuit Nunangat.

The most common reasons for hunting, fishing, trapping or gathering were for personal or family use (95%), for pleasure (82%), and to share with others in the community (64%). Only 14% of Inuit reported that they engaged in these activities for money or to supplement income.19

---

19. Percents do not add to 100% as respondents could identify more than one reason.
Income

Income is one of the most important social determinants of health (Tjepkema, Wilkins, Long, 2013; Commission on Social Determinants of Health, 2008; Auger et al., 2004). People with lower incomes generally experience worse health outcomes, including shortened life expectancy and a higher prevalence of disease (Tjepkema, Wilkins, Long, 2013; Commission on Social Determinants of Health, 2008).

According to the 2011 National Household Survey (NHS), the median household income for Inuit in 2010 was $74,021 while the median household income for the total population of Canada was $74,777.²⁰ ²¹ In Inuit Nunangat, the household income was $77,935; outside Inuit Nunangat it was $64,215 (see Chart 13).

²⁰ Data from the 2011 NHS are used in place of data from the APS because of a reduced sampling variability in the NHS.
²¹ The median income for a specified group of households is that amount which divides their income size distribution, ranked by size of income, into two halves.
Conclusions and future research

Conclusions
This report presents an overview of health status, health behaviours, access to health care and selected factors associated with health outcomes for the Inuit population aged 15 and older. A major element of the report is the geographic breakdown, which makes it possible to examine data for Inuit living in Inuit Nunangat (the Inuit homeland) and those living elsewhere. This is an important distinction, as the results for the two groups are generally significantly different.
Fewer than half of Inuit reported excellent or very good health, and those in Inuit Nunangat were less likely to report excellent or very good health than were those living elsewhere. More than four in ten Inuit had been diagnosed with a chronic condition by a health professional. Inuit living outside of Inuit Nunangat were more likely than those living in Inuit Nunangat to report a chronic condition, a difference that is likely associated with differences in access to health care professionals. Daily smoking was reported by 63% of Inuit living in Inuit Nunangat, compared with 29% of those outside Inuit Nunangat. Inuit living in Inuit Nunangat were more likely than were those living outside Inuit Nunangat to report non-consumption of alcohol. However, nearly identical percentages of Inuit living in and outside Inuit Nunangat—about one quarter—reported heavy drinking.

Inuit in Inuit Nunangat were more likely than those outside Inuit Nunangat to have experienced food insecurity and hunger, to live in dwellings needing major repair and with more than one person per room, to speak an Inuit language, and to have hunted, fished, trapped or gathered.

**Future research**

For Aboriginal people, including Inuit, health is a holistic concept encompassing not only the absence of disease, but also “physical, spiritual, mental, economic, emotional, environmental, social and cultural wellness of the individual, family, and community” (BC Ministry of Health, 2002).

While a number of social determinants of health were described in this report, each determinant could be examined individually through more in-depth analysis. Furthermore, many social determinants of health, both general and specific to Inuit, were not included in this analysis, such as education and livelihoods. Finally, mental health indicators could be explored as health outcomes and as social determinants of health.

In addition, social determinants of health are best understood in a multivariate context that accounts for their interconnections and the ways in which they work together to affect health outcomes.

Future research might also adopt theoretical approaches such as a life course perspective or a gender perspective.
