

Canada's unemployment mosaic, 2000 to 2006

Ernest B. Akyeampong

The unemployment rate is a well-known barometer of labour-market health. The rise in the national unemployment rate in the years immediately following the high-tech meltdown has been replaced by sustained annual declines, resulting in a rate of 6.3% for 2006. This is not only below the 6.8% registered during the boom, but a 30-year low as well.¹

Of course not all parts of the country have shared equally in the improvement. Some have done better, others worse. Normally, comparisons involve the 10 provinces or 5 regions of Canada, but within each, many distinct labour markets can be found. This article focuses on the 28 census metropolitan areas (CMAs) and the 10 provincial non-CMA areas (see *Data source and definitions*). Using the Labour Force Survey (LFS), the article first tracks unemployment rate dispersion for local labour markets (CMAs and non-CMA areas) between 2000 and 2006. It then examines the comparative labour market performance of these areas based on unemployment rates and rankings, and unemployment duration. Unemployment levels, labour force, and employment are provided in an appendix.

Unemployment rate dispersion rising

The impressive performance of the national unemployment rate in recent years hides considerable geographic disparities. For example, in 2006 the unemployment rate in the Québec CMA averaged 5.2% compared with 8.4% in nearby Montréal. Similarly, the unemployment rate in Kitchener (5.2%) was much lower than in Windsor (9.0%).

That the unemployment rate will differ by geographic area is generally understood. All things being equal, the dispersion is expected to narrow in periods of economic growth, when the national rate is usually falling

Ernest B. Akyeampong is with the Labour and Household Surveys Analysis Division. He can be reached at 613-951-4624 or perspectives@statcan.ca.

Measuring dispersion

For a number of reasons, gaps always exist between the national unemployment rate and rates registered by various CMAs and non-CMAs. An increase in the dispersion rate means the gap is widening, and vice versa. In this paper, dispersion rates for CMAs and non-CMA areas are calculated as a weighted mean of the differences between the area and national unemployment rates. Specifically, the absolute difference between each area rate and the national rate is multiplied by the area labour force. These products are summed and the total divided by the national labour force to produce aggregate dispersion. Finally, this is divided by the national unemployment rate to produce percent dispersion.

This is expressed algebraically as:

$$\frac{\sum_{i=1}^{38} |u_i - u_n| \cdot \frac{LF_i}{LF_n}}{u_n}$$

where

U_i = unemployment rate in area i

U_n = national unemployment rate

LF_i = labour force in area i

LF_n = national labour force

The dispersion of the average duration of unemployment was calculated in the same fashion.

(Guillemette 2006). However, the reverse has been the case in the current expansion, just as it was in the boom years of the late 1980s (Gower 1996). The variation around the national rate has tended to increase among CMAs and non-CMA areas in the past five years (2002 to 2006) as the national rate has drifted down (Charts A and B) (see *Measuring dispersion*).

Several reasons have been suggested for the rise in dispersion during the current expansion. First, the economic growth may not be strong or widespread (Guillemette 2006). The current expansion has been strongest in Western Canada (Cross and Bowlby 2006; White, Michalowski and Cross 2006), while

Chart A Canada's 2006 unemployment rate lowest in 30 years

Source: Statistics Canada, Labour Force Survey, 2000 to 2006

performance in some large metropolitan areas such as Toronto and Montréal has been more moderate. Others suggest that programs such as Employment Insurance may be discouraging the migration of some unemployed from underperforming areas to 'hot' labour markets, thereby accentuating the dispersion (Guillemette 2006).

Trends and patterns in unemployment rates

Starting from a low of 6.8% in the boom year of 2000, the national unemployment rate rose to 7.2% in 2001, in line with the high-tech meltdown. Unemployment peaked in 2002 (7.7%), stalled the following year at 7.6%, and then declined steadily to 6.3% in 2006 (Chart A). With few exceptions, most areas displayed similar trends (Table 1). The five areas with no clear trends were Prince Edward Island, Windsor, Thunder Bay, non-CMA Ontario, and Regina.

In both 2000 and 2006, Calgary registered among the lowest unemployment rates (4.5% and 3.2% respectively);² the highest rates were recorded in non-CMA Newfoundland and Labrador (21.3% and 19.3%).

Some areas emerged as perennial best performers, defined here as having the lowest unemployment rates in five of the seven years. Others were perennial poor performers. Nearly all the best performers were in the Prairies (Calgary, non-CMA Alberta, and non-CMA Manitoba, the exception being Victoria). The Alberta areas maintained their enviable position largely as a result of the prosperity brought on by the oil and gas industry and the increased activity in construction. The poor performers were non-CMA

Chart B Unemployment rate dispersion has been increasing since 2002

Source: Statistics Canada, Labour Force Survey, 2000 to 2006

Newfoundland and Labrador, Prince Edward Island, non-CMA Nova Scotia, non-CMA New Brunswick, and Windsor.

Both nationally and in a substantial majority of CMAs and non-CMA areas, the unemployment rate in 2006 was lower than in 2000. In eight areas, however, the opposite was true. Except for Montréal, the areas were in Ontario, a province hit by reduced activity in manufacturing overall and the auto industry in particular. High energy costs and reduced exports, due in part to the appreciating Canadian dollar, adversely affected these industries. A similar fate befell the manufacturing industries of Montréal; particularly hard-hit were its aerospace industry as well as the clothing and textile industry. Montréal also saw an employment drop in public administration.

Chart C Dispersion in the duration of unemployment dropped sharply between 2001 and 2004

Data source and definitions

The **Labour Force Survey (LFS)** collects information each month on labour market activity from the civilian, non-institutionalized population 15 years of age and over. The territories are excluded from the national total, as are persons living on Indian reserves. The survey samples approximately 54,000 households, with each remaining in the sample for six consecutive months.

A **census metropolitan area (CMA)** consists of an urban core with a population of 100,000 or more, together with adjacent urban or rural areas that have a high degree of economic and social integration with the core. Subtracting CMAs from the provincial total produces residuals consisting of smaller urban and rural areas. These are referred to as **non-CMA areas**. All of Prince Edward Island is defined as a non-CMA. While these provincial residuals obviously contain many local variations in labour market conditions, such detail is beyond the scope of this article.

The duration of unemployment describes how long (usually in weeks) someone has continuously been looking for a job. The LFS, by design, measures periods of continuous incomplete job search. Information on completed spells can be obtained from longitudinal data sources such as the Survey of Labour and Income Dynamics (SLID).

Losses in ranking centred in Ontario

One way of demonstrating the fortunes of the CMAs and non-CMA areas is by way of changes in unemployment rate rank between 2000 and 2006 (Table 2). By this measure, labour markets in Ontario fared worst. Of the 16 areas that saw a deterioration in rank over the period, 9 were in Ontario. In Quebec, Montréal and to a lesser

degree Sherbrooke also lost some ground, while in Saskatchewan, Regina and the non-CMA areas saw their rankings decline.

Of the five CMAs that registered the largest drops in ranking between 2000 and 2006, four were in Ontario's Golden Horseshoe (Oshawa, Hamilton, Toronto and

Windsor) and the fifth was Regina (Table 3). The better performance of the western labour markets is also evident in their strongly positive rank changes. Four of the five areas with the best improvement were in British Columbia: Victoria, Abbotsford, non-CMA British Columbia, and Vancouver. B.C.'s

labour market improvements came on the heels of gains in resource-based industries, construction and transportation, and in increased exports to the Far East, notably China. The Québec CMA also showed a significant improvement in ranking. Industries here registering respectable employment growth included public administration; information, culture and recreation; and transportation and warehousing.

Average unemployment duration falls in most CMAs

Average unemployment duration (weeks of continuous job search) provides one measure of the degree of difficulty faced by those searching for a job (Table 4).³

Unlike trends in the unemployment rate, a positive picture emerges from the average unemployment duration (Chart C). At the national level, duration fell by about 3 weeks (from 19.8 to 16.7 weeks) between 2000 and 2006. Declines were also registered in most areas

Table 4 Average duration of unemployment by region

(33). Whereas 8 areas registered a higher unemployment rate in 2006, only 5 areas had a higher average unemployment duration (Prince Edward Island, Saguenay, Oshawa, non-CMA Alberta, and Victoria). Indeed, except for Oshawa, all areas in Ontario had shorter durations in 2006. The rise in duration in Victoria is intriguing since this CMA was among those registering the best improvement in unemployment rate.

In addition to the fairly steep drop in average unemployment duration in most areas, the degree of dispersion tightened. In 2000, duration ranged from just over 12 weeks in Edmonton and non-CMA Alberta to 33 weeks in Trois Rivières (Table 4). By 2006, it ranged from around 8 weeks in Edmonton to about 22 weeks in Saguenay, Trois Rivières and Montréal.

Summary

The benefits of the current economic expansion have not been shared equally by the various CMA and non-CMA areas across Canada. The unequal distribution is clearly evident in the disparities observed in unemployment rate movements in the different geographical areas.

The past four years have witnessed an improvement in unemployment rates in many areas. Alberta and British Columbia CMAs and non-CMA areas especially have recorded significant improvements, reflecting the boom in oil, gas and other resource-based industries, as well as increased activity in construction and transportation. Only two CMAs, Windsor and Thunder Bay, have seen some recent deterioration or fluctuation in their unemployment rates. In Windsor,

this was primarily due to setbacks in manufacturing industries in general and the auto industry in particular. The overall result has been an increase in the unemployment rate dispersion over the past several years.

However, the overall picture emerging from the average duration of unemployment in the 2000s is more encouraging. Not only did the average weeks of continuous job search fall between 2000 and 2006 in most areas, the difference between the shortest and longest also shrank.

Perspectives

Appendix

Areas in Ontario registered the largest increases in numbers unemployed. This paper examined shifts in unemployment through the unemployment rate and ranking, both measures being abstract. However, the number of people unemployed is also of interest.

At the national level, the number of unemployed increased by 2.4% (26,000) between 2000 and 2006. Almost all of the 15 areas registering increases in unemployment numbers were located in Ontario (11) and Quebec (3). The other CMA recording an increase was Regina. Some of the increases were fairly large. For example, unemployment rose in Windsor by 81% (7,000), in Toronto by 38% (54,000), and in Oshawa by 38% (3,000). In Montréal, it rose by 19% (27,000).

The remaining 23 areas recorded decreases in unemployment, with significant declines being registered in Québec (-28% or -8,000), Edmonton (-22% or -6,000), Victoria (-40% or -4,000), and non-CMA British Columbia (-35% or -24,000).

Notes

1 Caution must be exercised when comparing recent LFS employment and unemployment estimates with those prior to 1976—when the questionnaire underwent significant changes.

2 In actual fact, in 2000 Calgary's unemployment rate (4.5%) was bettered by that of non-CMA Manitoba (4.3%).

3 The LFS average durations in Table 4 are, by survey design, for incomplete job search. These are shorter than completed search durations provided by other surveys such as the Survey of Labour and Income Dynamics (SLID). Notwithstanding, the LFS data still provide useful insights on labour market health.
