#### **Note of appreciation**

*Canada owes the success of its statistical system to a long standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.*

# Symbols

The following standard symbols are used in Statistics Canada publications:

- . not available for any reference period
- .. not available for a specific reference period
- ... not applicable
- 0 true zero or a value rounded to zero
- 0<sup>s</sup> value rounded to 0 (zero) where there is a meaningful distinction between true zero and the value that was rounded
- p preliminary
- r revised
- x suppressed to meet the confidentiality requirements of the *Statistics Act*
- E use with caution
- F too unreliable to be published

## Custom tabulations of SLID data

For clients with specialized data needs, custom tabulations can be produced on a cost-recovery basis. Contact Client Services, Income Statistics Division (1 (888) 297-7355 or (613) 951-7355; [income@statcan.ca](mailto:income@statcan.ca)).

## Remote access to SLID data

Remote access is an initiative that enables external researchers to access and use SLID data.

Under this arrangement, researchers contact the Income Statistics Division to indicate their interests in remote access to SLID data and provides a short abstract outlining the objectives for their research. Upon approval of their access request, researchers are provided with a copy of the SLID retrieval software (SLIDRET), as well as an empty SLID database structure.

Researchers write and test their own computer programs, then send these programs to Statistics Canada over the Internet. We submit their programs, vet the output for confidentiality, and e-mail the results back. This process opens up our complex data set to even more researchers and increases research volume.

This service is an alternative to Statistics Canada's Research Data Centres and regional offices.

Contact Client Services, Income Statistics Division (1 (888) 297-7355 or (613) 951-7355; [income@statcan.ca](mailto:income@statcan.ca)).

## **Research Data Centres**

Research Data Centres are part of an initiative by Statistics Canada, the Social Sciences and Humanities Research Council (SSHRC) and university consortia to help strengthen Canada 's social research capacity and to support the policy research community.

# Highlights

## 2003 income: an overview

- After-tax family income remained virtually unchanged for the second year in a row in 2003. After five consecutive years of strong growth, average after-tax income reached a plateau in recent years for almost every type of family in Canada.
- The three main components of after-tax income -- market income, government transfers and personal income taxes -- all remained more or less stable.
- Average after-tax income for families of two people or more edged down slightly to an estimated \$59,900 from \$60,400 in 2002, after adjusting for inflation. This slight decline is not considered statistically significant.
- In contrast, between 1996 and 2001, after-tax income for these families grew at an average annual rate of 3.2%.
- For single-parent families headed by women, average after-tax income held steady at about \$30,000. Between 1996 and 2001, their income gains were among the strongest primarily because of rising employment rates among single mothers.
- An estimated 726,000 families were living in low income in 2003, 8.4% of the total. This rate was down slightly from 8.6% in 2002 and well below the peak of 12.1% in 1996.
- An estimated 843,000 children aged 17 and under, or 12.4% of the total, were living in low-income families in 2003, compared with more than 1.3 million in 1996. The rate was unchanged from 2002, but well below the peak of 18.6% in 1996.

## Main components all hold relatively steady

- The three main components of after-tax income - market income, transfers from governments and personal income taxes - were all relatively unchanged from 2002.
- Market income is the sum of paid employment and self-employment earnings, and income from investments and pensions, and represents the lion's share of family income, particularly for non-elderly families. In 2003, market income for families of two people or more reached \$64,900, approximately the same level as the previous year.
- Families of two or more people paid an estimated \$12,800 on average in personal income taxes in 2003, a marginal \$200 less than in 2002 (after adjusting for inflation).
- Government transfers cover a range of programs such as Employment Insurance (EI), Old Age Security, child tax benefits and so on. The amounts received by the average family remained unchanged from 2002, at an estimated \$7,800. In 1996, average transfers amounted to \$8,300 per family.
- The number of families receiving EI benefits remained constant in 2003 after rising 19% during the previous two years. Most of this gain was related to expanded

benefits that became effective at the end of 2000 for people seeking parental leave. In 2003, average EI benefits paid to receiving families remained unchanged from previous year at \$6,100.

### **After-tax income unchanged for female single-parents**

- On average, the after-tax income for the estimated 541,000 single-parent families headed by women remained unchanged at \$30,000 in 2003, mainly as the result of their market income, which held steady at \$23,800.
- This stability follows a strong average gain of 52% in market income for female lone-parent families between 1996 and 2001, equivalent to an annual growth rate of 8.7%. This was one of the largest increases among the various types of families.
- About 82% of women in these families had earnings in 2003, the same as the year before, but well above the corresponding figure of 62% in 1996.
- The low-income rate for female lone-parent families in 2003 was about four times the average for all families. Of the 541,000 female lone-parent families in 2003, about 38% or 208,000 were living in low income. This proportion was stable from 39% in 2002.

### **Seniors: Growth of after-tax income for senior families**

- Average after-tax income of senior families in which the major income earner was aged 65 or over remained unchanged at \$43,800 in 2003. However, this was a 10% gain from 1996 primarily as a result of an increase in their market income.
- In 2003, senior families received on average an estimated \$20,900 in government transfers, accounting for 42% of their total income before taxes.
- Seniors living on their own had an average after-tax income of \$23,000 in 2003.
- The low income rate among seniors has continued its downward trend since the early 1980s. In 2003, 6.8% of seniors were living below Statistics Canada's low-income cut-off, down from 21.3% in 1980 and 9.8% in 1996.
- The low-income rate for unattached senior women was 19% in 2003, compared with 15% for their single male counterparts.

### **Unattached individuals: Moderate gain in market income**

- Unattached individuals recorded the biggest gain in market income of any group in 2003. On average, these people earned \$25,600 from employment, investments and pensions, up 4.1% from \$24,600 in 2002.
- However, this increase did not translate into an equivalent gain in after-tax income. That is because government transfers to this group declined, while their personal income taxes went up. In fact, they paid \$5,300 on average in personal income taxes in 2003, compared with \$4,900 the year before.
- As a result, after-tax income for unattached individuals rose insignificantly from \$25,300 to \$25,600.
- In 2003, some 29% of these individuals were living in low income, virtually the same rate as the year before. However, this rate was substantially below the 37% in 1996.

### **Income inequality: Government transfers and taxes helped reduce disparities**

- One measure of income inequality is the ratio of income received by the 20% of families with the highest after-tax income compared with the 20% of families with the lowest after-tax income.
- In 2003, for market income, this ratio was about 12.9 to 1.0. That is, the 20% of families with the highest after-tax income received about \$12.90 in market income for every \$1.00 received by the 20% of families with the lowest after-tax income.
- However, taxes and transfers moderate the differences between the quintiles of the income distribution. After taxes and transfers, the one-fifth of families with the highest after-tax income received \$5.50 for every \$1.00 received by the one-fifth with the lowest.
- Among unattached people, the one-fifth with the highest after-tax income received \$21.60 in market income for every \$1.00 received by the 20% with the lowest after-tax income. After taxes and transfers, this ratio fell to \$8.40 for every \$1.00.

### **Provinces: After-tax income remained stable**

- In general, average after-tax income for families of two people or more did not change significantly in any province between 2002 and 2003.
- As in previous years, average after-tax income was highest among families in Ontario at \$66,500, followed by those in Alberta who averaged \$64,900. They were the only two provinces in which the levels were above the national average of \$59,900.
- After-tax income was lowest among families in Newfoundland and Labrador at \$47,100.
- In 2003, families of two or more people in Newfoundland and Labrador received, on average, government transfers estimated at \$11,800, the highest in Canada and well above the national average of \$7,800.
- The low-income rate among families was lowest in Prince Edward Island at 3.7%, and highest in British Columbia at 11.6%, compared with the national average of 8.4%.

# Introduction

This report examines family income and low income in Canada. The data prior to 1996 are drawn from the Survey of Consumer Finances (SCF). Beginning with 1996, the data are taken from the Survey of Labour and Income Dynamics (SLID).

Every few years, estimates produced by the combined program of the Survey of Labour and Income Dynamics (SLID) and the Survey of Consumer Finances (SCF) undergo a historical revision. This year's revision is the result of three modifications.

- All estimates, back to 1990, are adjusted to population projections based on the 2001 Census population counts.
- Starting with 1990 estimates, wages and salaries are benchmarked to the distribution of wages and salaries derived from the T4 statement of remuneration paid file.
- The 1992-base low income cut-offs (LICOs) they have been revised, resulting from a revision of the 1992 Family Expenditure Survey. SLID and SCF estimates were revised from 1980. Along with the two changes described above, this has an impact on levels of low-income statistics.

For more information on the 2003 historical revision and on its impact on estimates please consult the Notes and definitions section of the document *Survey of Labour and Income Dynamics - A survey overview* (product number 75F0011XIE) or the research document *Survey of Labour and Income Dynamics: 2003 historical revision* (forthcoming in June 2005).

The publication is organized into chapters, each dealing with a specific income concept. Chapter 2 examines market income, also known as "income before transfers". It represents the money people earned from the labour market, investments and private pensions. Chapter 3 looks at government transfer payments, focusing on specific groups or family types (such as the elderly, lone-parent families and families without an earner) that are the target beneficiaries of most income security programs. Chapter 4 deals with the total income of Canadian families, examining the role of government transfers in total income. Chapter 5 presents information on income tax and how it varied by family type. Chapter 6 examines after-tax income. The joint effect of transfers and income taxes is assessed. Chapter 7 focuses on income inequality. Chapter 8 concentrates on low income in Canada, including low income persistence.

The companion product to this publication -- a compilation of tables called *Income Trends in Canada* (product number 13F0022XCB and 13F0022XIE) -- shows data tables for the period starting with 1980. It also contains data for the provinces in addition to 15 metropolitan areas. Tables on earnings (the major component of market income) and other related income concepts or statistics are also included.

When assessing data trends over time, there is always the choice of time period on which to make comparisons. Obviously, the analytical section at the beginning of chapters focuses on what's "new", the most recent year of data available. But it also draws on trends over the previous several years. The present edition shows stability of income for families and individuals between 2001 and 2003, after 5 year upward trend (1996-2001).

Structural changes regarding income, such as in the distribution of incomes across the population, tend to require a longer time period to reveal notable changes. When commenting on the income distribution in Canada, such as quintile analysis or the Gini Coefficient, we often compare the last few years. For analysis at the provincial level, it is again preferable to look at a longer trend for the purpose of separating

real changes in income levels from estimate variation that could be caused by smaller sample sizes at the provincial level.

Quintile analysis is frequently used in this publication. Quintile data are produced by ranking economic families of two persons or more from lowest to highest by the value of their income, grouping the ranked families into five equal-numbered groups, or "quintiles", and then calculating statistics on each of the groups. The income concept used in this publication to rank families is always after-tax income, so they are called after-tax income quintiles. This way of defining the quintiles has the advantage of holding the population in each quintile constant while comparing different characteristics, such as market income versus after-tax income. But one can also analyse market income using market income quintiles, or total income using total income quintiles, as shown in table 701 of the product *Income Trends in Canada*, (product number 13F0022XCB and 13F0022XIE).

Income is not adjusted for family size. Since changes in family size can account for changes in average incomes, it is worth noting that the average number of members in economic families of two or more persons decreased slightly over the period of analysis, from about 3.14 in the early 1990s to 3.06 in 2003.

All the figures included in this report (unless otherwise stated) are sample survey estimates. To factor in inflation when comparing income levels across time, all the income estimates are expressed in constant dollars of the last year for which data are presented.

# Market income

Market income includes the earnings that Canadians receive from employment. Also included in market income is investment and private pension income. For the majority of Canadians, particularly those of “working age” (aged 16 to 64), money from employment constitutes the highest proportion of market income. In 2003, 88% of aggregate market income came from employment.

### Labour market situation in 2003

Events that would have affected our economy in 2003 included the rapid appreciation in the Canadian dollar against the US dollar, SARS, the power outage in Ontario and the US and the war in Iraq. Nonetheless, the labour market ended up improving in 2003, albeit modestly.

According to data from the Labour Force Survey, there was a rise of 0.7% in the employment rate (i.e. the number of people employed compared to the working age population) over 2002, reaching a historical high of 62.4% in 2003. This increase was mainly due to the 0.6% growth in the participation rate, which climbed to 67.5% in 2003. In contrast, the unemployment rates remain virtually unchanged, reaching 7.6% in 2003 compared to 7.7% in 2002. In 2003, real per capita GDP increased slightly by 1.1%<sup>1</sup>.

Market income is closely tied to labour market conditions. These conditions affected the market incomes of the various family types and individuals in different ways, as shown in the following paragraphs.

### Little change in market income in 2003 for Canadian families

Average market income for Canadian families of two or more people was estimated at \$64,900 in 2003, virtually unchanged from 2002 after adjusting for inflation (as measured by changes in the Consumer Price Index). This period of quasi-stability started in 2002 with a -0.3% change in market income. This represented a pause after five consecutive years of growth. After its low in 1996, when it was estimated at \$56,300, by 2001, average market income had increased by more than 17% (an average of 3.2% per year).

### A generalized pause in market income in 2003 for the main family types

Market income for two parent families was estimated at \$80,400 in 2003, virtually unchanged from 2002. Market income had stagnated since 2001 for this type of family. Between 1996 and 2001, average market income for all two parent families increased by 19%, an average annual increase of 3.5%.

1. Statistics Canada – Catalogue no. 13-213

**Chart 2.1**

**Average market income of economic families and unattached individuals, 1981 to 2003**

2003 constant dollars

Between 1996 and 2001, average market income for female lone parent families rose by 52%, an average annual increase of 8.7%. Between 2001 and 2002, it fell slightly by 10%, levelling off at \$23,800 in 2003.

Despite the relative stability in their market income between 2001 and 2003 (+3.5% from 2001 to 2002 and -1.0% from 2002 to 2003), senior families (in which the major income recipient is 65 or older) saw their average market income increase by 12% between 1996 and 2001. During this period, average market income changed from \$25,600 to \$28,600, reaching \$29,300 in 2003.

**Market income for married couples with no children**

The average market income of married couples with no children who are not seniors rose from \$61,800 in 1996 to \$70,900 in 2001, an increase of 15%. However, between 2001 and 2003, this income fell slightly by 5.6%, reaching \$66,900 in 2003.

**Chart 2.2**

**Average Market Income, Canada and Provinces, Percentage Change between 1996 and 2003**

**Chart 2.3**

**Average market income by major family type, 1996 and 2003**

2003 constant dollars

**Market income trend varied among quintiles**

Between 1996 and 2001, average market income for economic families of two or more people in the lowest income quintile (quintiles based on after-tax income) rose by \$2,700 (+32%), while in the highest income quintile, this increase came to \$24,700 (+19%). Between 2001 and 2002 and

between 2002 and 2003, average income in these two extreme quintiles remained practically the same, levelling off in 2003 at \$11,500 for the lowest income quintile and \$148,800 for the highest income quintile.

**Chart 2.4**

**Share of market income by quintiles, 1996 and 2003**

**Average market income for families of two or more people virtually unchanged in 2003 in most provinces**

From 2001 to 2002, as from 2002 to 2003, in most provinces, average market income for families of two or more people remained virtually unchanged. The only significant increase was in Saskatchewan, with a 2.5% increase in market income from \$55,900 to \$57,300 in 2003. Nonetheless, from 1996 to 2001, average market income increased from a minimum of 6.3% in Prince Edward Island to a maximum of 20.2% in Alberta. In 2003, Ontario, at \$73,200, remained the province with the highest market income, followed by Alberta, with \$72,000.

**Increase of the market income of unattached individuals**

Unattached individuals recorded the biggest gain in market income of any group in 2003. On average, these people earned \$25,600 from employment, investments and pensions, up 4.1% from \$24,600 in 2002. From 1996 to 2003, market income of unattached persons increased by 25%.

**Increase in market income of unattached working age women since 1996**

In 2003, the average market income of unattached females of working age was \$27,500, compared to their male counterparts at \$31,900. In 1996, the market income of unattached women was \$20,700, and \$26,600 for their male counterparts. Thus, the difference in average market income between males and females of working age changed from \$5,900 in 1996 to \$4,400 in 2003.

## **Change in market income for unattached individuals by quintile**

**B**etween 1996 and 2003, average market income for unattached individuals in the third quintile (quintiles divided based on after-tax income) increased by 53%, the largest percentage increase, from \$10,200 to \$15,600, while the highest income quintile's increased by \$12,400, the largest dollar increase. The average market income of unattached individuals in this group was estimated at \$71,400 for 2003.

## **Some stability in average market income in several Canadian provinces**

**W**ith the exception of Alberta (-10.2%), the average market income of unattached individuals remained virtually unchanged in 2003 in most Canadian provinces. In 2003, the highest average market income was in Ontario, at \$30,200, followed by Alberta, at \$24,700.

## ***Government transfers***

Government transfers cover a range of programs. For example, Employment Insurance provides temporary income assistance to those who lose their job or are absent for reasons of illness or the birth of a child. The Canada Pension Plan and the Quebec Pension Plan are the two public pension plans in Canada. Old Age Security, including the Guaranteed Income Supplement, provides financial support to seniors. Child tax benefits and other child credits or allowances are aimed at families with children. Other government transfers include social assistance from provincial and municipal programs, Workers' Compensation benefits, the GST/HST Credit and provincial refundable tax credits such as the Quebec and Newfoundland and Labrador sales tax credits.

The implicit transfer rate shows the amount received from all these sources as a proportion of total income (before tax). Unless otherwise specified, the average amounts of transfers are calculated for the total population (both recipients and non-recipients); they would be higher if non-recipients were excluded.

In addition to what is provided in this chapter, Chapter 4 and Chapter 7 include data on government transfers.

### **Average government transfers decreased slightly for unattached individuals in 2003**

Average government transfers for all families of two persons or more have remained constant since 2001 at \$7,800. Unattached individuals, on the other hand, saw their average government transfers diminished from \$5,600 in 2002 to \$5,400 in 2003, a \$200 decrease. This can be explained by a market income increase of 4.1% for unattached individuals.

### **Four in five families receive government transfers**

Just over four out of five families of two persons or more (82%) received government transfers in 2003. The proportion is similar for unattached individuals (81%). For the last ten years, these numbers have been declining slowly from almost 90% in 1993. The average amounts paid to recipient families and unattached individuals have been stable since 1996. In 2003 they were \$9300 and \$6600 respectively.

### **Little change in Employment Insurance benefits payments for families**

The number of families receiving Employment Insurance benefits (EI) remained constant in 2003 after rising by 19% over the two previous years. This increase was related to policy changes that became effective at the end of 2000 for persons seeking parental leave.

The average EI benefits paid to receiving families was also stable in 2003 at \$6,100. Consequently, when compared with 2002, the aggregate EI payments for families change little and remained at approximately \$11.5 billion in 2003.

The story is somewhat different for unattached individuals (not usually eligible to receive parental benefits). While the number of unattached individuals receiving EI benefits saw a 6% increase with 424,000 recipients in 2003 from 399,000 in 2002, the average amount received decreased,

from \$5,500 in 2002 to \$4,700 in 2003. Consequently the aggregate payments decreased by 10%, from 2002, to about \$2 billion in 2003.

### Transfers to seniors remained stable

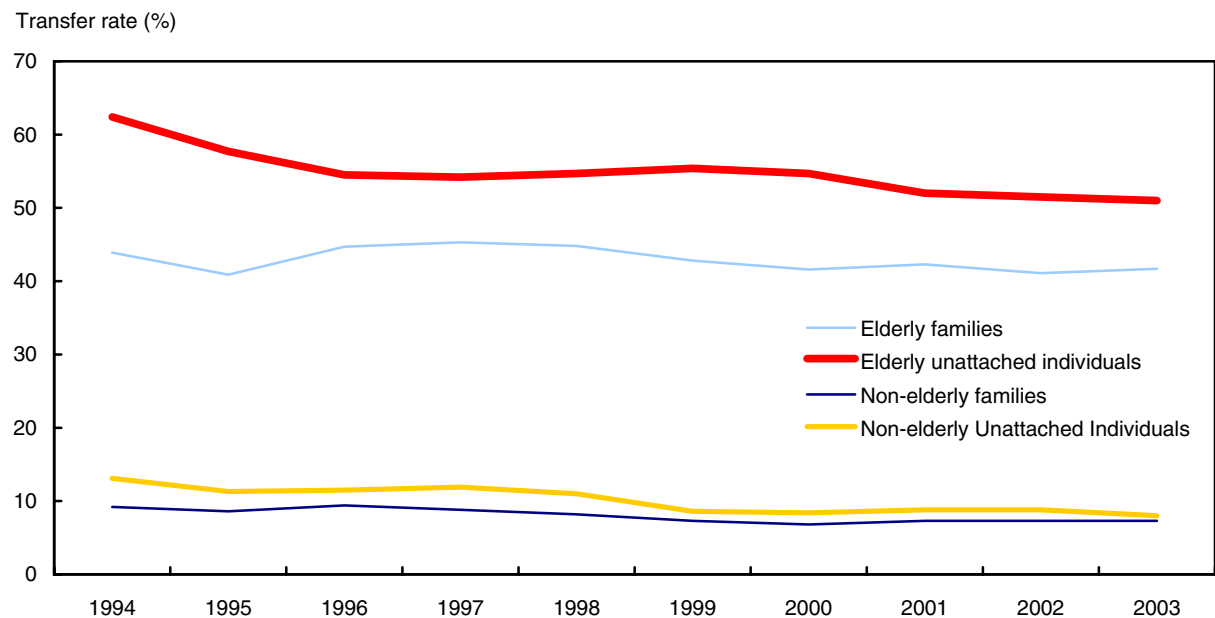

Government transfers typically make up a large proportion of the total income received by seniors, this proportion is called the implicit transfer rate. Just over half of unattached seniors' total income comes from government transfers mainly from the Canada and Quebec Pension Plan benefits, Old Age Security pension and Guaranteed Income Supplement. The implicit transfer rate has remained stable over the last few years.

Elderly families received an estimated \$20,900, on average, in government transfers in 2003, compared to an average \$5,600 for non-elderly families. In 2003, elderly families received 42% of their total income before tax in the form of transfers, while non-elderly families had corresponding implicit transfer rates of 7%.

The trend over the past two decades in government transfers to elderly families fluctuated less than transfers to non-elderly families. Since most seniors are retired, government transfers to this group are less tied to labour market conditions than transfers to families with children or other people of working age. Two of the main transfers to seniors are the Canada and Quebec Pension Plan benefits and the Old Age Security pension, both of which are relatively independent of a person's or family's income level. The Guaranteed Income Supplement — the needs-based portion of Old Age Security — provides an additional low-income supplement if necessary.

Chart 3.1

### Implicit transfer rates for seniors are higher than for non-seniors, 1994 to 2003

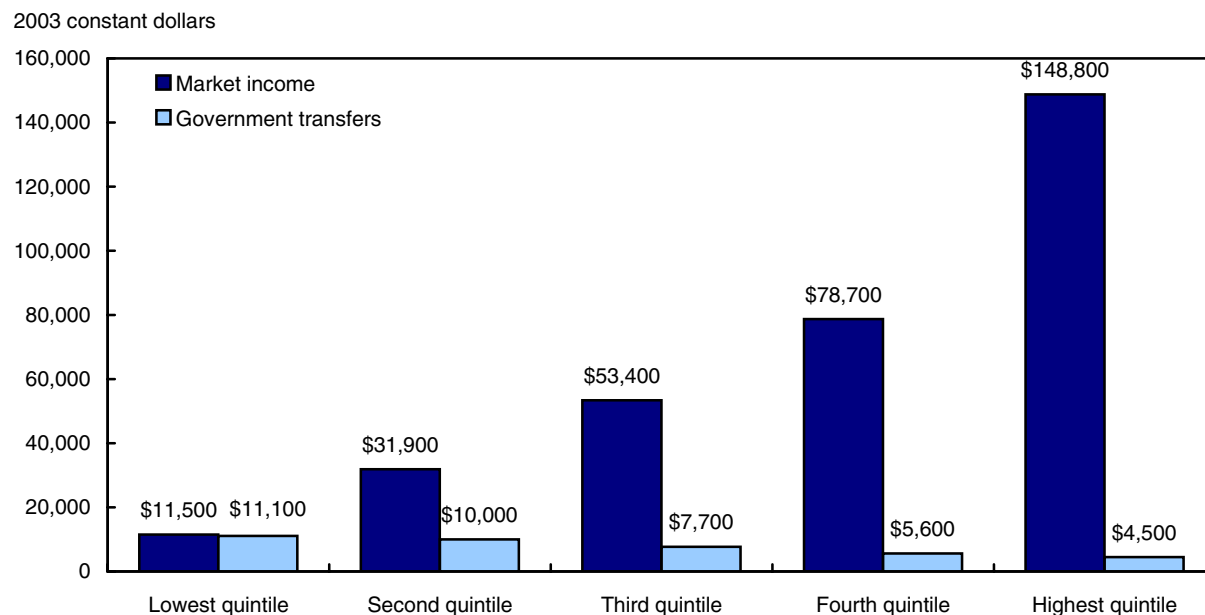

### The lowest-income families received 28% of government transfers

Many types of government transfers are designed to supplement the incomes of lower-income families and individuals. This is evident in the distribution of transfers over the population when ranked from lowest to highest after-tax income. The share of transfers paid to families in the lowest after-tax income quintile is typically the highest – it was 28% in 2003. The share to the second lowest quintile was

the second highest, at 26%, and so on for every quintile, with the highest income quintile families receiving 12% of all transfers paid to families. These relative shares have remained quite steady for the last ten years.

**Chart 3.2**

**Market income and government transfers for families by after-tax income quintiles, 2003**

**Transfers to families with children in the absence of earnings**

Two-parent families with no earnings for the whole year received on average \$15,600 in government transfers in 2003, or 68% of their total income in the form of transfers. Among female lone-parent families without earnings, 85% of their total income came from government transfers (\$13,500); the remainder came mostly from other income, including support payments from former spouses.

**Child Tax Benefits paid to families increased gradually between 1996 and 2001 then remained at the same level until 2003**

Among all recipients of child tax benefits, the average amount each family received from federal and provincial sources rose from an estimated \$1,900 in 1996 to \$2,500 in 2001 — an increase of about 32%. Over those six years the rules used for calculating the benefit amounts have been modified, leading to a larger average benefit received. The most notable changes in the average amount of child benefits received per family were in 1998 and in 2001. Since 2001 the level of average Child Tax Benefit received remained unchanged.

## ***Total income***

Total income is the sum of market income and government transfers.

Considering all sources of income, after adjusting for inflation, economic families of two persons or more received an estimated \$72,700 in average total income in 2003, almost unchanged when compared to the two previous years. Over the five year period, 1996 to 2001, total family income grew by 14% at an average annual increase of 2.7%. Average total income for unattached individuals has gradually grown by 17% since 1996, or equivalently at 2.3% annual rate. It was estimated at \$30,900 in 2003.

In 2003 and 2002, average total income of families in all provinces experienced no significant changes from the previous year. Since 1984, Ontario still remained the province where families had the highest average total income of \$80,900, followed by Alberta at \$78,300. Newfoundland and Labrador remained as the province having the lowest total income with \$56,100.

### **After five years of growth, average total income for non-elderly families remains constant since 2001**

In 2003, non-elderly families received on average an estimated \$76,400 in total income, unchanged since 2001. Between 1996 and 2001, their average total income went up by 15%. Unattached males of working-age (16 to 64 years of age) received in 2003 an estimated average total income of \$34,400; 15% more than in 1996. While the total income of unattached females of working-age (16 to 64 years of age) grew in this period by 26% their average total income was still lower at \$30,100.

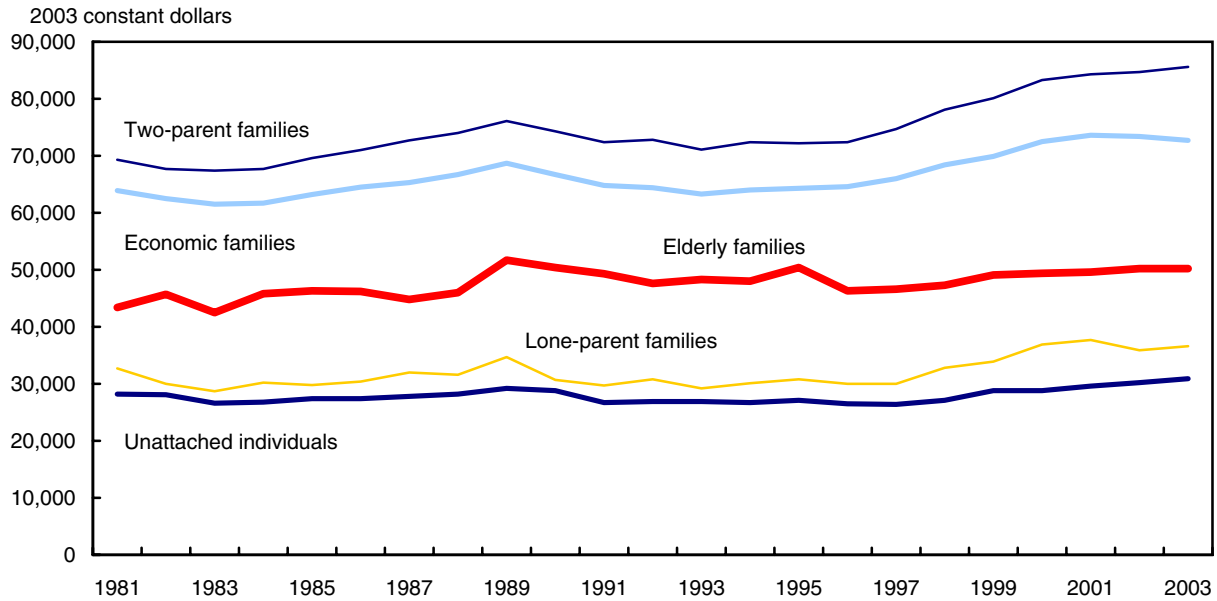

### **Senior families' total income remained stable from 2002 to 2003**

The average total income of families, whose main income earner was a senior, remained unchanged from 2002 to 2003 at \$50,200. Among elderly unattached individuals, men's average total income climbed by 5.7% since 1996. In 2003, average total income was estimated at \$29,600. The picture is slightly different for senior unattached women: even though their total income grew 8.8% from 1996 reaching \$24,800 in 2003; it is lower than their male counterpart by \$4,800.

In aggregate terms, in 2003, market income accounted for 58% of the total income of senior families. The rest of their income came primarily from transfers such as public retirement pensions with 19% and Old Age Security at 20% of their total income.

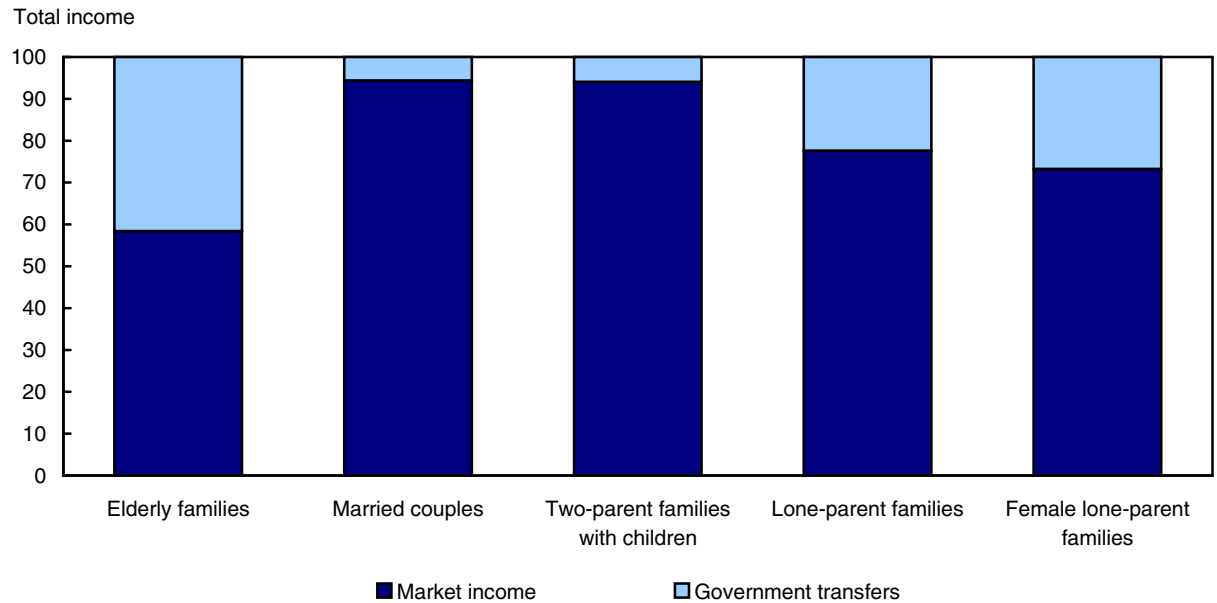

**Chart 4.1**

**Average total income of families and unattached individuals, 1981 to 2003**

**Chart 4.2**

**Market income made up majority of total income for non-elderly families in 2003**

**Income redistribution: impact of government transfers**

In 2003, families in the lowest income quintile received only 3.6% of aggregate market income, but their share of total income was larger at 6.2%. Conversely, families in the highest income quintile received 46% of aggregate market income but 42% of total income.

Before government transfers, those in the highest income quintile received, on average, \$12.90 for each \$1 earned by those in the lowest quintile. After transfers, this ratio was reduced to \$6.80 to \$1. Government transfers also reduced the income differences between various family types. Before transfers in 2003, the average income of non-elderly families was 2.4 times that of elderly families. After transfers, this ratio was reduced to 1.5.

**Chart 4.3**

**Government transfers increased shares of total income for lower quintiles, 2003**

1. Source: Income Statistics Division, Statistics Canada.

2. Includes economic families of two persons or more and unattached individuals.

3. Starting in 1999, all social assistance amounts reported to the survey by one or both individuals in a couple are reassigned to the female spouse, or the older of the two spouses in the case of a same-sex couple. This caused a shift in some of the time series for social assistance data for individuals, for example, an increase in the average amount received, and a decrease in the number of recipients. The time series showing the aggregate amount of social assistance is not affected, nor are the data at the family or household level.

4. Includes economic families and unattached individuals. An economic family is defined as a group of two or more persons who live in the same dwelling and are related to each other by blood, marriage, common law or adoption. An unattached individual is a person living either alone or with others to whom he or she is unrelated, such as roommates or a lodger.

## Income taxes

Income taxes include both federal and provincial taxes. The implicit tax rate is the average or aggregate amount of taxes expressed as a percentage of their average or aggregate total income.

### Average amount of income tax paid by families stable after a decline in 2001

Canadian families of two persons or more paid an estimated \$12,800 on average in income tax in 2003, or about \$1,600 less than in 2000 (after adjusting for inflation). In 2000 the average income taxes paid by families reached its highest point since 1980 (the earliest year for which comparable data are available). There had been an 8% decline in 2001, a year when the federal government and several provincial governments made changes in their income tax policies. There has been virtually no change in the average income tax paid between 2002 and 2003.

### Average taxes paid by unattached individuals increasing

Average taxes paid by unattached individuals increased by 8.2% (from \$4,900 to \$5,300) at the national level between 2002 and 2003. This is related to their increase in market income. Between 1996 and 2003, average taxes paid by unattached individuals increased by 15% from \$4,600 to \$5,300 while their market income grew by 25%.

Chart 5.1

### Average income tax of families and unattached individuals, 1981 to 2003

2003 constant dollars

## **Four family types, representing over half of all non-elderly families, had an implicit tax rate of about 20%**

The implicit tax rate for Canadian families was 17.6% in 2003, virtually no change from 2002 and a small decrease when compared to 2001. For several years before 2001, the rate varied between 19 and 20 percent. Unattached individuals registered an increase, posting an implicit tax rate of 17.1% in 2003, up from 16.2% in 2002. This is related to their increase in market income. Over the 1990s the rate varied from 17.0% to 18.5%.

In 2003 families of two or more persons in which the major income earner was under age 65 (non-elderly families) and unattached individuals aged less than 65 had average implicit tax rates of 18.1% and 18.5% respectively.

In contrast, elderly families and elderly unattached individuals had lower average implicit tax rates of 12.9% and 12.6%, respectively. The difference between seniors and the rest of the population is consistent given that retirement income is on average lower than income received over the course of one's working-age years—the ratio of tax to total income during retirement is also considerably lower on average.

Several family types have similar implicit tax rates. In 2003, among families in which the major income earner was under age 65, single-earner and dual-earner couples without children, single-earner and dual-earner two-parent families all paid, on average, about one-fifth of their total income in income tax (19.2%, 20.0%, 19.2% and 20.5%, respectively). These four family types represent 57% of all non-elderly families.

## **Shares of income tax by income quintile**

In 2003, families of two or more, in the highest after-tax income quintile paid on average \$35,300 in income tax, or just over half (55%) of the aggregate amount of income tax paid by Canadian families. As an indication of the progressive tax-transfer system, these high-income families had a larger share of market income (46%) relative to their share of after-tax income (39%). Meanwhile, families at the lowest end of the distribution paid on average \$1,100 in income tax. These lower income families had a smaller share of market income (3.6%) relative to their share of after-tax income (7.2%). It is interesting to note that families in third and fourth quintiles held approximately the same share of market income (16.5% and 24.3% respectively) relative to their after-tax income (17.5% and 23.3% respectively).

**Chart 5.2**

**Shares of total income and income tax of families by after-tax income quintiles, 2003**

**Chart 5.3**

**Average income tax by family type, 2001 and 2003**

**British Columbia, Ontario and Quebec experienced the largest decrease in average income tax paid by families between 2000 and 2003**

The implicit tax rate (percentage of total income paid in taxes) is determined in part by the amount of total income and the federal and provincial taxation policies. In 2001, the federal government and several

provincial governments made important changes in their income tax policies leading to a decrease in the implicit tax rate in most provinces. In the two years that followed (2002 and 2003) there was no clear upward or downward trend. In fact there has been virtually no change in the average income tax paid between 2002 and 2003. Looking back to the year 2000, a year before changes in taxation policy, the families of two persons or more, living in three largest provinces, British Columbia, Ontario and Quebec, registered the largest decrease in average income tax paid between 2000 and 2003. In 2003 the average income tax paid by families was 81%, 87% and 88% of the amount they had paid in 2000, for these three provinces respectively.

For unattached individuals the changes in average income tax paid were noticeably correlated to variations in their average market income. The average market income growth by 51% in Nova Scotia, by 38% in Ontario and 28% in Quebec between 1996 and 2003, translated to increase in average taxes paid (77%, 36% and 22% respectively).

## *After-tax income*

After-tax income is defined as total income (market income plus government transfers) less income taxes. Thus, after-tax income reflects income redistribution through transfers and taxes.

### **After-tax income remains stable for a second year**

The average after-tax income for families of two or more people was \$59,900 in 2003, remaining practically unchanged after adjustment for inflation, compared to 2002 (-0.8%). This stability follows five consecutive years of increases from 1996 to 2001 (+16.4%).

The average after-tax income of female lone-parent families increased by 28%, from \$25,000 to \$31,900, between 1996 and 2001. This increase in after-tax income was explained by the increase in market income, which rebounded by 52% between 1996 and 2001. As in the case of families of two or more people, female lone-parent families' after-tax incomes stabilized at \$30,000 between 2002 and 2003.

Families of two or more people whose main income earner was under 65 years of age received average after-tax income of \$62,600 in 2003, which is practically unchanged from the previous year (-0.8%).

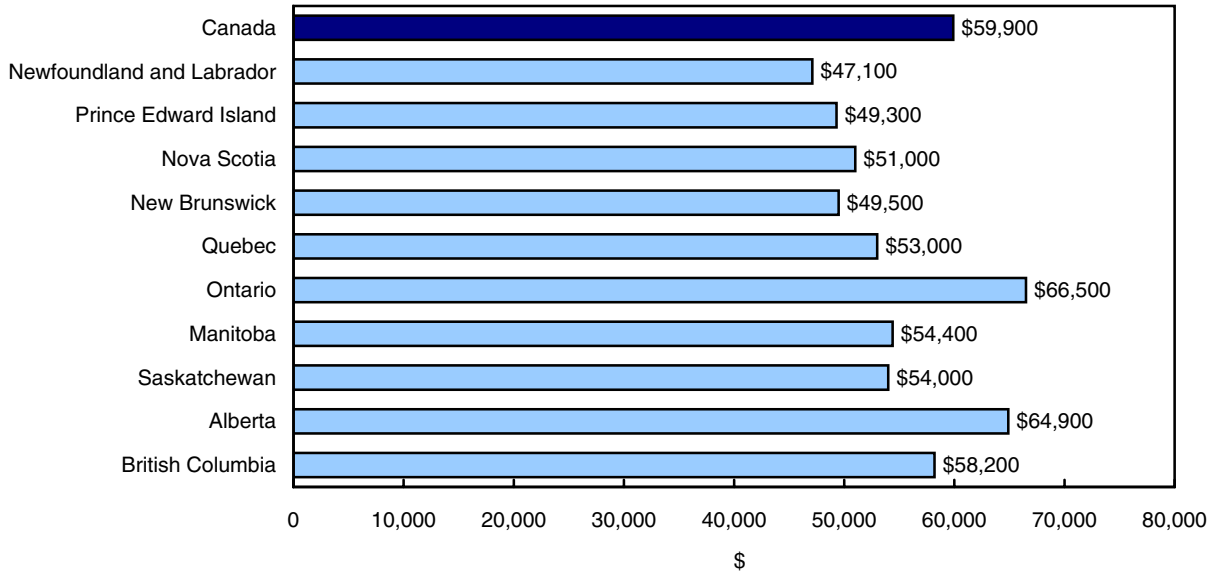

Senior families (whose main income earner was aged 65 or over) saw an 8.8% increase in their after-tax income between 1996 and 2001. Yet this small increase seems quite insignificant compared to the increases faced by non-senior families (18%), such as single income married couples, whose after-tax income increased by 22% during this period.

Average after-tax income for single people came to \$25,600 in 2003, a 17% increase over 1996 (\$21,900).

**Chart 6.2**

**Averages in market income, total income and after-tax income of families followed similar trends, 1981 to 2003**

2003 constant dollars

**Ontario and Alberta, still in the lead with family after-tax income**

Ontario and Alberta ranked first and second, respectively, for family after-tax income between 1996 and 2003. While all provinces saw their average after-tax income rise during

this period, since 1996 Ontario and Alberta actually increased their lead over the national average. Their leads over the national average increased from \$5,200 to \$7,100 for Ontario and from \$2,800 to \$6,000 for Alberta between 1996 and 2001. In general, after-tax income remained virtually unchanged in all provinces between 2002 and 2003.

### Government transfers and taxes helped reduce the disparities between the different types of families

In 2003, families of two or more people received an average \$7,800 in government transfers and paid \$12,800 in taxes, a net contribution of \$5,000. This contribution represented 7.7% of their income before transfers and taxes; which means that the family retained, on average, 92% of its market income.

Two earner couples with no children retained the lowest ratio, with 82% of their market income. Inversely, for families whose main income earner was a senior, and for female lone parent families, this ratio was 149% and 126%, respectively. In other words, these families received more in government transfers than they paid in taxes.

Personal income taxes and government transfers reduced the income disparities among the various types of families. While average market income for elderly families was 41% of average market income for non senior families, their after-tax income came to 70% of the latter group's income. Average market income of female lone parent families was 46% of the average market income of all other families, but rose to 62% after transfers and taxes.

Chart 6.3

#### Change in average market income and after-tax income by family type, 1996 and 2003

Chart 6.4

**Female lone-parent families earned only 30% of average market income, but 43% of average after-tax income of two-parent families, 2003**

**The average after-tax income of families in the first and last quintiles remained stable in 2003**

In order to facilitate comparisons between higher and lower income families, we organized families by after-tax income and then divided them into five equal-numbered groups, which we call quintiles. Thus, the 20% of families with the lowest after-tax income are in the first quintile, while the 20% of families with the highest after-tax income are in the last quintile.

In 2003, families of two or more people in the highest-income quintile received \$12.90 for every market income dollar received by families in the lowest income quintile. After government transfers and taxes, the difference came to \$5.50 for every dollar.

For unattached individuals, the reduction was even more significant. Individuals in the highest income quintile received \$21.60 for every market dollar earned by unattached individuals in the lowest income quintile. After transfers and taxes, unattached individuals in the highest income quintile received an average \$8.40 for every dollar received by the lowest income quintile.

Average after-tax income for families of two or more people remained stable between 2002 and 2003 for families in the lowest income quintile as well as for those in the highest income quintile. Thus, in 2003, the average after-tax income of families in the first quintile was \$21,500 and that for families in the last quintile was \$118,100.

**The disparity between the lowest and highest income families increased between 1996 and 2002, and remained stable between 2002 and 2003**

Between 1996 and 2001, the after-tax income of families in the lowest income quintile increased less (+16%, or \$2,900) than their market income (+32%, or \$2,700). After-tax income and market income increased less in the highest income quintile, with the former increasing by 21% (an increase of \$20,800) and market income by 19% (an increase of \$24,700).

In 1996, for families of two or more people, the difference in after-tax income at the two quintile extremes was \$80,900. In 2002, the gap increased, reaching \$99,500, an increase of 23%. At \$96,600, this gap between the first and last quintiles remained practically unchanged in 2003.

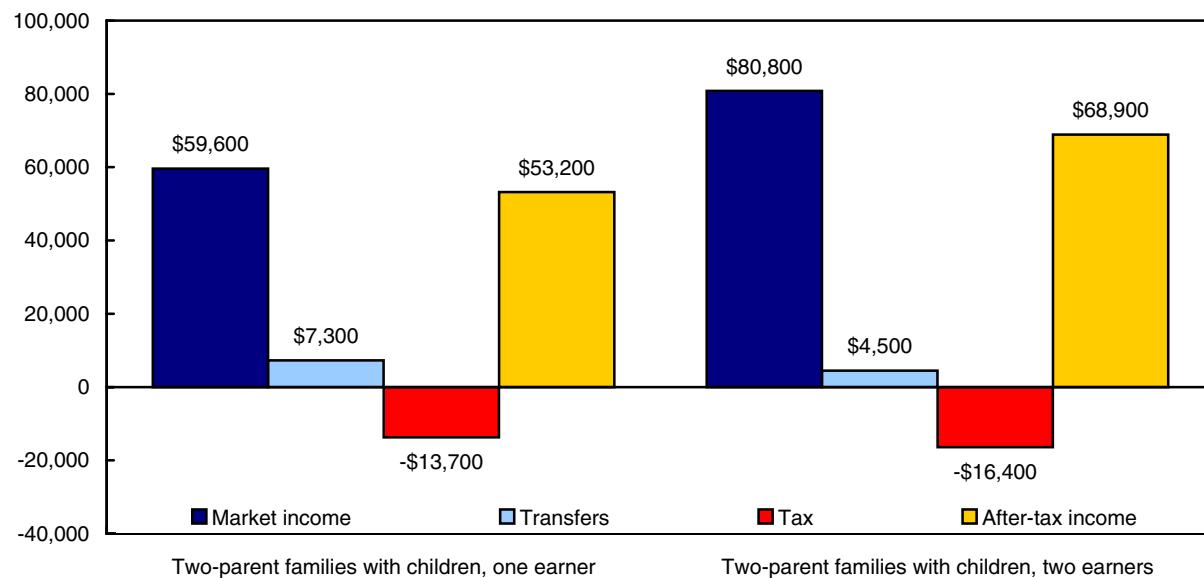

In 2003, the after-tax income of unattached individuals in the lowest income quintile was \$6,700 and \$56,300 in the highest income quintile. Since 1996, after-tax income had increased by 9.8% (an increase of \$600) for unattached individuals in the lowest income quintile, while for those in the highest income quintile, it increased by 22% (an increase of \$10,000).

The disparity between the lowest and highest income quintiles for unattached individuals changed from \$40,200 in 1996 to \$49,600 in 2003, an increase of 23.4%.

## ***Family income: income inequality***

This chapter highlights broad trends in income inequality, both on a market income basis and an after-tax income basis. The difference between these two concepts of income is government transfers and income taxes, so the chapter also provides information on the redistributive impact of the tax-transfer system.

### **Has income inequality changed in recent years?**

This question can be answered in a few ways. One way is to look at income in absolute terms: did the differences in income across the population become larger or smaller in dollar terms? It can also be looked at in relative terms: how did the distribution of income change in terms of the share held by the families with the lowest and the highest income. Depending on how the income of all families changed, each approach could lead to a different conclusion. The following analysis illustrates changes in inequality among Canadian families using both points of view.

In absolute terms, i.e., in dollar terms, the disparities in after-tax income became wider over the years from 1996 to 2001. This happened mainly because of a greater improvement in the average income of the one-fifth of families with highest income (top quintile). In 2002 and 2003, the distribution of after-tax income remained about the same as in 2001.

In relative terms, the distribution of after-tax income for the whole period from 1997 to 2003 changed very little.

### **Incomes across the distribution stagnated after 2001, after they improved from 1996**

Since changes in aggregate income can have an impact on the conclusions to be made about inequality, it is important to recognize that average after-tax income for families has been on the rise since 1996. Most of the increase occurred over the five years from 1997 to 2001. Average after-tax income for families stabilized between 2001 and 2003, at about \$60,000.

When the population of families is broken down each year into five equal-sized groups or “quintiles”, from lowest after-tax income to highest after-tax income, it can be seen that all five quintiles shared to some extent the increases in after-tax income from 1996 to 2001. This trend ceased in 2002 when none of the quintiles experienced significant growth in after-tax income. The stagnation continued in 2003 when all five quintiles saw almost no change in their after-tax income. The same is true for market income.

### **Widening of the gap ceased in 2003**

The gap is the dollar difference between the average after-tax income of the highest and lowest quintiles. This difference increased by 23% between 1996 and 2002. However, in 2003, this gap stabilized at \$96,600. Over the period from 1996 to 2003, the average after-tax income of the highest 20% of families of two or more persons rose by an estimated \$18,500 or 19%. Although the lowest quintile had a \$2,800 increase in average income, this was a 15% improvement. The middle three quintiles had increases of 13% to 14% in their average after-tax income. In short, the absolute gains of the highest quintile were the largest, in dollar terms and as a percentage of the income they

started with. The lowest quintile had the smallest gains in dollar terms, but had the second highest gains as a percentage of the income they started with.

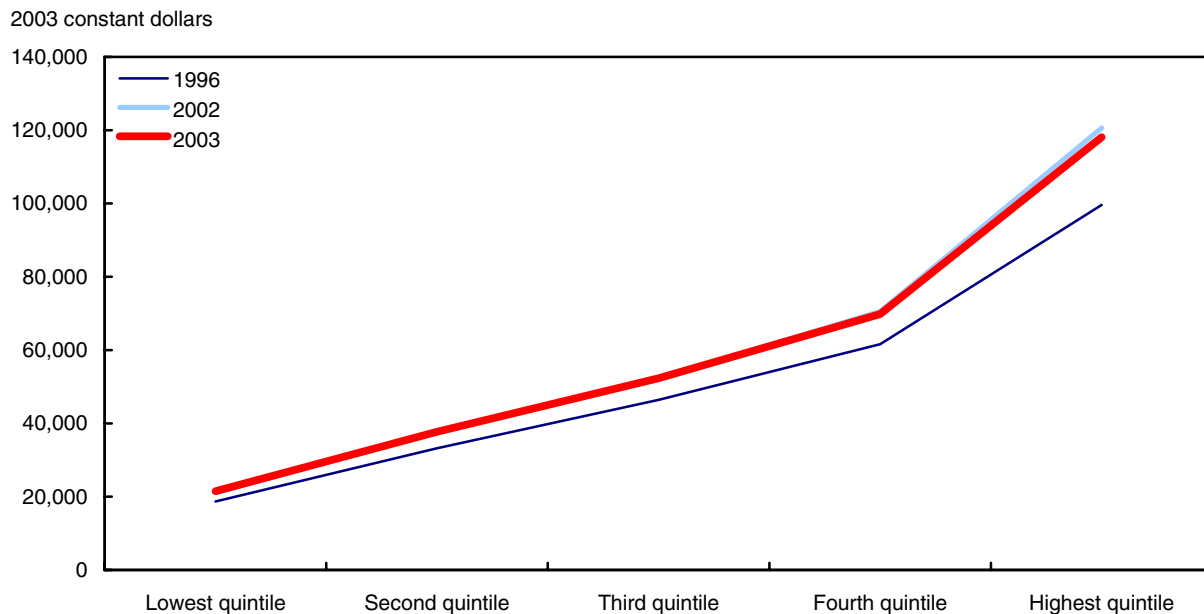

Looking at market income over the same period, the bottom two quintiles (still defined on an after-tax basis) had much larger percentage improvements in income than they did on an after-tax basis, but their market income is so low that even a small variation in dollar terms appears as a large percentage change. For example, the lowest quintile had an increase in average market income of 37% between 1996 and 2003, while the second quintile had an increase of 19%. But in dollar terms, the lowest quintile gained \$3,100 in average market income and the second quintile gained \$5,100, contrasted with a gain by the highest quintile of \$20,600. For the highest quintile, this gain represented a 16% increase in their average market income.

Chart 7.1 shows the average after-tax income for families in each quintile, at three points in time covering the period 1996 to 2003. A line drawn between the points of each adjacent pair of quintiles shows the degree of inequality in the distribution between the five groups of the population, in absolute terms. An increase in the steepness of the line between two years suggests that the distribution has become less equal, while a flatter line suggests it has become more equal.

Between 1996 and 2002, the line in Chart 7.1 shifted upwards and became steeper. This is true for all segments of the line, but especially between the fourth and fifth quintiles. This suggests that the inequality of the distribution of income grew across all five quintiles, but especially between the highest quintile and all other families. Between 2002 and 2003, the line remained the same for all quintiles except the highest quintile where it became slightly flatter. This suggests that the inequality of the distribution did not change between 2002 and 2003.

**Chart 7.1**

**Average after-tax income of families by quintiles, for years 1996, 2002 and 2003**

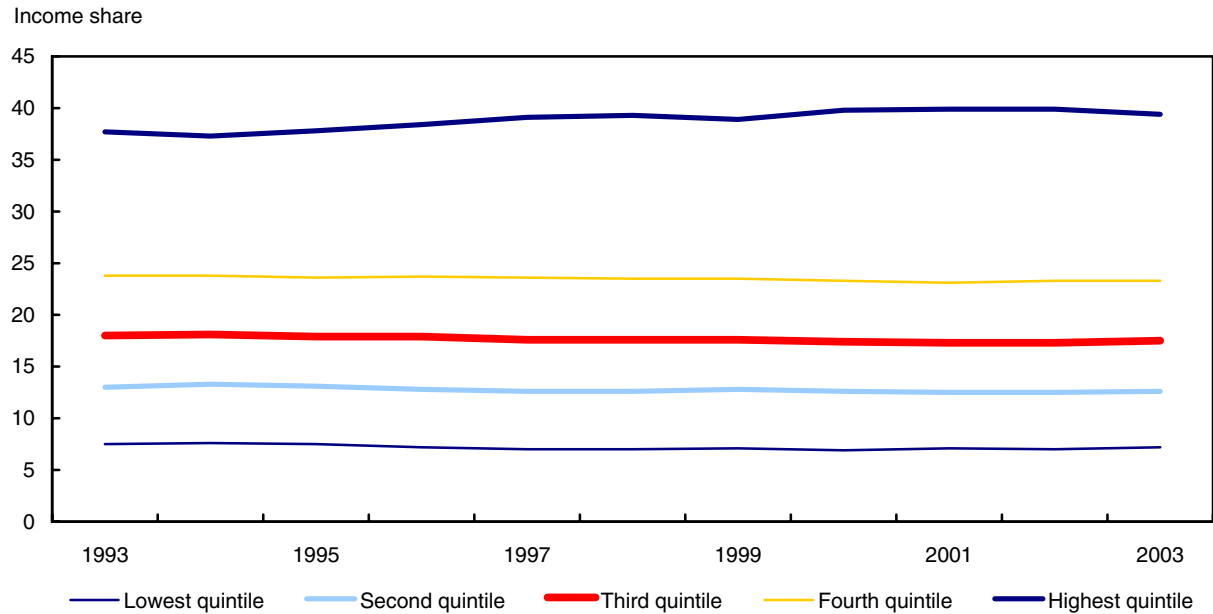

**Income inequality in relative terms**

By expressing the income of each quintile as a share of the income of all families, we concentrate on relative changes among quintiles. Any increase to a particular quintile is necessarily a decrease for another quintile. How did the shares of income received by lower-, middle-, and higher-income families evolve in the last several years?

There was a very small and gradual shift in favour of the highest quintile families up to 2000, as their share of after-tax income rose from 38% to 40%. These gains were due to slight deteriorations of after-tax income of the third and fourth quintile families. Starting in 2000, the highest quintile families' share stabilized at 40% and then it fell to 39% for 2003.

**Chart 7.2**

**AShares of aggregate after-tax income by quintiles, 1993 to 2003**

**Increasing ratio of the top to the bottom**

Another relative measure of income inequality is the ratio of average income of the highest income families to that of the lowest income families. This measure focuses on the two ends of the income distribution. Again, after-tax income quintiles are used here to identify these two groups of families.

This ratio shows quite starkly the impact that taxes and transfers have in moderating differences between the outer ends of the distribution. In terms of market income, the ratio of average income received by the families in the highest quintile versus those in the lowest quintile was 12.9 to 1 in 2003, i.e., \$12.90 held by the highest quintile for every one dollar held by the lowest quintile. However, after taxes and transfers, the ratio was much lower, 5.5 to 1.

As for the movement in the after-tax income ratio of top to bottom, it remained stable at about 5.0 to 1 for several years up to 1995. It then rose to 5.6 in 1997. It then fluctuated between 5.5 and 5.8 in the years leading up to 2003, when it was estimated to be 5.5 to 1.

While this measure would suggest that income inequality increased between 1995 and 1997, the interpretation of changes in this ratio has to be done carefully. A given dollar increase or decrease for the lowest quintile will always be larger in percentage terms than for the highest quintile. With the ratio measure in particular, when the income of the lower quintile is rising, the value of the ratio can decrease, even while the gap in dollar terms between the top and the bottom is widening.

This apparent contradiction occurred, in fact, when the ratio for market income fell between 1998 and 2000. Over that period, the gap in average market income between the lowest 20% of families and the highest 20% increased by over \$7,900, as a result of a \$2,500 increase for the lowest quintile and a \$10,400 increase for the highest quintile - clearly a larger dollar gain for

the higher quintile. But because it represented a 28% increase for the lowest quintile and only a 7.4% increase for the higher quintile, the ratio of average market income of the top to the bottom declined; it fell from 15.5 to 1 in 1998, to 13.1 to 1 in 2000. Historically, the ratio of average market income of the top to the bottom was about or slightly above 15 to 1 up until 1999. After 1998, it varied between 13 and 14 to 1 and attaining the lowest level in a decade (12.9 to 1) in 2003.

**Chart 7.3**

**Ratio of average income of the highest quintile families to the lowest, showing market income and after-tax income, 1993 to 2003**

Average income ratio:  
Highest to lowest quintile

**The Gini coefficients declined for market income and remained stable for after-tax income in 2003**

The Gini coefficient is a number between zero and one that measures the degree of inequality in the distribution of income. Again, this is a relative measure of inequality. The coefficient would register zero (perfect equality) for a population in which each member received exactly the same income and it would register a coefficient of one if one member received all the income and the rest received none. Even though a single Gini coefficient value has no simple interpretation, comparisons of the level over time or between populations are very straightforward: the higher the coefficient, the higher the inequality of the distribution, and vice versa.

The Gini coefficients for families were fairly stable from 1992 to 2003, at about 0.44 for market income. The coefficients for after-tax income for families were also fairly constant (0.30) from 1992 to 1995; they then rose slightly in 1996 and 1997. From then on, the Gini coefficients for after-tax income remained relatively stable at the 0.32 to 0.33 level.

**Chart 7.4**

**Gini Coefficients for families, 1993 to 2003**

## *Low income*

A person in low income is someone whose family income falls below Statistics Canada's low income cut-offs (LICOs). The cut-offs reflect an income level at which a family is likely to spend significantly more of its income on food, shelter and clothing than the average family.

Low income cut-offs have been calculated using both total income (that is, income after government transfers but before taxes), and after-tax income. The analysis below provides after-tax low income information. Statistics Canada considers this measure to be preferable for two main reasons. First, income taxes and transfers are essentially two methods of income redistribution. The before-tax rates only partly reflect the redistributive impact of Canada's tax/transfer system, by including the effect of transfers but not the effect of income taxes. Second, since the purchase of necessities is made with after-tax dollars, it is logical to use people's after-tax income to draw conclusions about their overall economic well-being.

When is someone counted as being in low income? Low income cut-offs depend on family size since larger families need more income to meet their needs. The cut-offs also take into account the varying costs by community size. In 2003, a family of four living in a city with a population of half a million or more would be counted as low income if the total of the after-tax income for all family members fell below the cut-off of \$31,277. For the same family living in a rural area, the cut-off was \$20,460.

### **Low income rate for families in 2003 has stabilized**

The low income rate for families of 2 persons or more fell for five consecutive years starting in 1997. In 2002, it increased to 8.6% from 7.9% in 2001 and then remained stable at 8.4% in 2003, an estimated 726,000 families.

Since 1998 there has been a slight improvement in the financial situation of families living below the low income cut-off. On average, in 2003, a family would have needed an additional \$7,000 to bring their income up to the low income cut-off compared to \$7,600 in 1998.

After reaching a maximum of 38% in 1997, the low income rate for unattached individuals showed a decreasing trend to 29% in 2003. The low income rate for unattached elderly females was at 19%, still well above the Canadian population (16%). However, this rate has been gradually decreasing for over two decades from 57% in 1980. The rate for unattached elderly males has been decreasing from a high of 47% in 1980 to 15% in 2003.

### **Low income rate varies by family composition and number of earners**

The low income rate of elderly families was the lowest among major family types at 2.7%. The rate for non-elderly families was 9.3% in 2003, representing a decrease of 4.2 percentage points since 1996. For married couples with no children, the low income rate varies from 2.9% with two income earners to 29.3% with no earners. Overall, married couples with no children had a low income rate of 6.5% in 2003.

For the 3 million two-parent families with children, the low income rate was 6.6%. Out of all two-parent families, almost two-thirds had two earners (1,902,000) in 2003. The low income rate for two-parent families with two earners was 3.6% (down from 3.8% the previous year). Of the estimated 448,000 two-parent families with one earner, 16.8% were in low income. Although relatively

few in number, 81% of the 50,000 two-parent families with no earners experienced low income in 2003. Over the past two decades, this rate has not dropped below 69% (the rate in 1997).

**Chart 8.1**

**Majority of families with no earner were in low income, 2003**

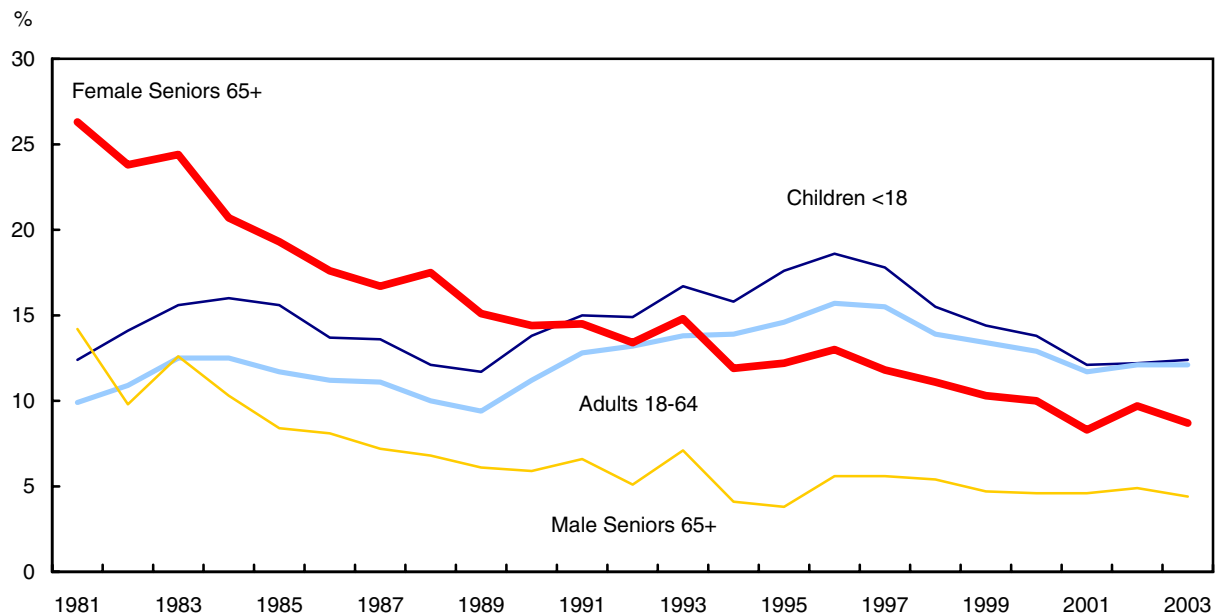

**Low income rate for female lone-parent families decreases**

From 1996 to 2001 the low income rate for female lone-parent families decreased from 53% to 34%. The low income rate for female lone-parent families grew to 39% in 2002 and then diminished slightly to 38% in 2003. Of the 541,000 female lone-parent families in 2003, 208,000 families were living in low income in 2003. About 82% of lone-parent families headed by women had earnings in 2003 (about the same rate as in 2002) while in 1996 the corresponding figure was 62%. Although the low income rate of female lone-parent families with one earner was about four times the average for all families (32% versus 8.4%), they were much better off than lone mothers without earnings; 86% of the latter experienced low income in 2003.

On the other hand, the low income rate for lone-parent families headed by men halved since 1996, when it stood at 25%. By 2003, it went down to 12.6%.

Chart 8.2

Low-income rates of children, adults of working age, and seniors, 1981 to 2003

Low income rate for persons unchanged between 2002 and 2003

After climbing throughout the early 1990s, the prevalence of low income among all Canadians peaked in 1996, at 15.7%, and then declined to 11.6% in 2002. In 2003, 11.5% of all individuals were living in low income (about 3.6 million persons). Low income was more prevalent among women than men (12.1% versus 10.9% in 2003).

About 843,000 children under 18 were living in low income families in 2003, down from 1,304,000 in 1996. On an after-tax basis, the proportion of children living in families in low income has been falling from 18.6% (peak in 1996) to 12.1% in 2001. Since then, it did not change significantly. In 2003, the percentage of children in low income was at 12.4%.

Just over half of all children in low income families (843,000) live in two parent families (433,000). The low income rate of children living in two-parent families (7.7%) was much lower than that of children living in female lone-parent families (41%) in 2003. There were 365,000 children in low income in female lone parent families.

The low income rate among seniors has continued its downward trend since the early 1980s. In 2003, 6.8% of seniors were living below Statistics Canada's low-income cut-off, down from 21.3% in 1980 and 9.8% in 1996.

Among seniors aged 65 and over, low income rates and trends varied by gender. Until 2000, low income rates for senior women have been more than double those for senior men. Since 2001, the rates for senior women have been less than twice those for senior men. In 2003, the low income rate for women aged 65 and over was 8.7%, the respective rate for men was 4.4%. Historically, the low income rate for senior men has been dropping from about 15% in 1980 until it stabilised at around 5% in the mid 1990's. For senior women, the low income rate has been diminishing gradually since 1980, when the rate was about 27%.

Seniors living on their own, as unattached individuals did not fare as well as those living in families: 18% were in low income in 2003, compared with only 2.2% of seniors living in an economic family. The rate was 19% for unattached elderly women and 15% for unattached elderly men.

People in the 18 to 64 age range accounted for just over two-thirds of the total low income population. Their low income rate was close to the average rate for the population at large: 12.1% of individuals in this age group were in low income in 2003.

## Crossing the LICO line

A family's income often changes substantially over time. A breadwinner may lose a job or a second family member may enter the labour market. The family itself may experience a change, such as marital separation, which often affects income. The birth of a child, an older relative joining the household or even a move to a larger city can affect income needs. Such changes can cause a family to "cross the line", moving into or out of low income.

Of all persons in low income in 2002, one-third was no longer below the line in 2003, while the remaining two-thirds stayed in low income both years. Of all people in low income in 2003, 34% had not been in low income the year before. In short, there is clearly some turnover in the low income population from one year to the next, even when the overall low income rate does not change much, as was the case between 2002 and 2003. At least for some, low income is not a persistent state. However, this level of turnover also means that, over a longer period, the number of people that experience low income at some point in time is much greater than one might conclude based on annual low income rates.

## Low income touched more than one in five people over a six-year period

According to data referring to the period from 1996 to 2001, a quarter (25.4%) of all Canadians experienced low income at some time over a six-year period. This reflects the fact that, for some, low income is a transitory experience. About 8.6% experienced one year of low income and 5.4% experienced two years (not necessarily consecutive). At the other extreme, 3.4% of the population was in low income throughout the full six years. Among all those below the cut-off at some time during the six-year period, the average spent 2.8 years in low income.

Among children under 18 years of age in 1996, 30.2% were in families that experienced low income at some time over the 1996 to 2001 period. About 9.6% were in low income for one year, 3.3% for all six years. The average number of years in low income for children was 2.8, about the same as the average for all persons.

At some time during the 1996 to 2001 period, 13.7% of persons 65 years or older in 1996, experienced low income. While this rate is below the 25.4% rate for the whole population, 4.3% seniors experienced six years of low income which is above the rate for all Canadians (3.4%).

**Chart 8.3**

**Persons experiencing low income at least one year at some time during six years from 1996 to 2001**

## *Background Tables*

This chapter shows the population estimates underlying the income time series covered in the publication. Table 9.1 provides data on the number of persons by selected family types. Table 9.2 presents data on the number of families by selected family types.

Table 9.1-1

## Selected family types, Canada — Number of families

	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
	estimates in thousands									
<b>Economic families, two persons or more</b>	<b>7,882</b>	<b>8,005</b>	<b>8,078</b>	<b>8,145</b>	<b>8,206</b>	<b>8,283</b>	<b>8,373</b>	<b>8,466</b>	<b>8,584</b>	<b>8,665</b>

# Notes and definitions

## Income

This section reviews the definitions of the main income concepts and their components. In order to highlight the relationships between them, this section is organized according to the "Classification of income" ( see text box — Classification of income by source).

### Classification of income by source

#### **M**arket income

##### Earnings

Wages, salaries and commission

Self-employment income

Farm

Non-farm

Investment income

Retirement pensions

Other income

#### **(plus) Government transfers**

Child tax benefits

Old Age Security and Guaranteed Income Supplement/Spouse's Allowance

Canada Pension Plan/Quebec Pension Plan benefits

Employment Insurance benefits

Social assistance

Workers' compensation

GST/HST Credit

Provincial/territorial tax credits

Other government transfers

#### **(equals) Total Income**

#### **(minus) Income tax**

#### **(equals) After-tax Income**

### The concept of income

There are several important inclusions and exclusions in the concept of income:

- The concept of income covers income received while a resident of Canada or as relevant for income tax purposes in Canada. This excludes some, but not all, foreign income.
- Retirement income received as a regular pension or annuity during retirement is included, while cash withdrawals from private pension plans, including Registered Retirement Savings Plans (RRSPs), prior to retirement, are excluded.
- Realized capital gains from financial investments are excluded.
- In the Canadian System of National Accounts (CSNA) and the present income classification, taxes on capital gains are included in income taxes, as are taxes on RRSP withdrawals. Both capital gains (the taxable portion thereof) and RRSP withdrawals figure in the calculation of taxes, but are not part of total income in the CSNA or in SLID's Classification of income.

- SLID's classification of income includes all refundable tax credits and benefits, including those that are not considered for income tax purposes, such as child tax benefits, the Goods and Services Tax Credit/Harmonized Sales Tax Credit, and other provincial or territorial tax credits. There are other smaller differences between SLID's total income and total income defined for tax purposes (see Other income and Other government transfers ).
- Contributions to Employment Insurance and the Canada and Quebec Pension Plans, both federal programs, are not included in income taxes, nor are they deducted from income to arrive at after-tax income. However, the CSNA recently revised its definition of taxes on production to include these payroll taxes, in accordance with international recommendations on national accounting.

## **Market income**

**M**arket income is the sum of earnings (from employment and net self-employment), net investment income, (private) retirement income, and the items under "Other income". It is equivalent to total income minus government transfers. It is also called income before taxes and transfers.

### **Earnings**

**T**his includes earnings from both paid employment (wages and salaries) and self-employment.

### **Wages, salaries and commissions**

**T**hese are gross earnings from all jobs held as an employee, before payroll deductions such as income taxes, employment insurance contributions or pension plan contributions, etc. Wages and salaries include the earnings of owners of incorporated businesses, although some amounts may instead be reported as investment income. Commission income received by salespersons as well as occasional earnings for baby-sitting, for delivering papers, for cleaning, etc. are included. Overtime pay is included.

Military personnel living in barracks are not part of the target population in SLID.

### **Self-employment income**

**T**his is net self-employment income after deduction of expenses. Negative amounts (losses) are accepted. It includes income received from self-employment, in partnership in an unincorporated business, or in independent professional practice. Income from roomers and boarders (excluding that received from relatives) is included. Note that because of the various inclusions, receipt of self-employment income does not necessarily mean the person held a job.

Self-employment income is subdivided into farm self-employment income and non-farm self-employment income. Farm self-employment income is reported by individuals who operate their own or a rented farm, either on own account or in partnership. Included are money receipts from the sale of farm products as well as related supplementary and assistance payments from governments. Income in kind is excluded.

### **Investment income**

**T**his includes interest received on bonds, deposits and savings certificates from Canadian or foreign sources, dividends received from Canadian and foreign corporate stocks, cash dividends received from insurance policies, net rental income from real estate and farms, interest received on loans and mortgages, regular income from an estate or trust fund and other investment income. Realized capital gains from the sale of assets are excluded. Negative amounts are accepted.

### **Retirement pensions**

**T**his is retirement pensions from all private sources, primarily employer pension plans. Amounts may be received in various forms such as annuities, superannuation or RRIFs (Registered Retirement Income Funds). Withdrawals from RRSPs (Registered Retirement Savings Plans) are not included in

retirement pensions. However, they are taken into account as necessary for the estimation of certain government transfers and taxes. For data obtained from administrative records, income withdrawn from RRSPs before the age of 65 is treated as RRSP withdrawals, and income withdrawn from RRSPs at ages 65 or older is treated as retirement pensions. Retirement pensions may also be called pension income.

### **Other income**

This sub-total includes all items of market income not included elsewhere. Among them are support payments received (also called alimony and child support). The coverage of other items depends at least to some extent on the method of income data collection, whether from administrative income tax records or by interview. Those items which are included on line 130 of the T1 tax return are well covered. These include, but are not restricted to, retirement allowances (severance pay/termination benefits), scholarships, lump-sum payments from pensions and deferred profit-sharing plans received when leaving a plan, the taxable amount of death benefits other than those from CPP or QPP, and supplementary unemployment benefits not included in wages and salaries.

### **Government transfers**

Government transfers include all direct payments from federal, provincial and municipal governments to individuals or families. See the table Classification of income for a list of the government transfers identified separately in the latest reference year. It should be noted that many features of the tax system also carry out social policy functions but are not government transfers per se. The tax system uses deductions and non-refundable tax credits, for example, to reduce the amount of tax payable, without providing a direct income.

### **Child tax benefits**

Federal child tax benefits began in 1993 and replaced both the federal Family Allowances and the Child Tax Credit. Several provincial and territorial programs have since been introduced, in addition to Quebec family allowances which already existed before 1993. To be eligible, a person must have the primary responsibility for the care and upbringing of one or more children under the age of 18. Most benefits are calculated by setting a maximum amount per family or per child and reducing that total by a certain percentage of the family's net income.

The programs which were explicitly accounted for in the data were the federal basic benefit and National Child Benefit Supplement (together called the Canada Child Tax Benefit, began in 1998), the Newfoundland and Labrador Child Benefit (began in 1999), the Nova Scotia Child Benefit (began in 1998), the New Brunswick Child Tax Benefit (began in 1997), the New Brunswick Working Income Supplement (began in 1997), the Quebec Allocation familiale (began in 1981), the Quebec Allocation à la naissance (began in 1998), the Ontario Child Care Supplement for Working Families (began in 1998), the Saskatchewan Child Benefit (began in 1998), the Alberta Family Employment Tax Credit (began in 1997), the BC Family Bonus (began in 1996), and the BC Earned Income Benefit (began in 1998).

### **Old Age Security (OAS)**

The Old Age Security (OAS) pension is targeted to Canadian residents aged 65 and over. OAS recipients who have little or no other income may also receive the federal Guaranteed Income Supplement (GIS) and their spouses, if aged 60 to 64 (and not yet eligible for OAS and GIS themselves), receive the Spouse's Allowance.

### **Canada Pension Plan (CPP) and Quebec Pension Plan (QPP)**

The CPP and QPP are compulsory contributory social insurance programs that provide a source of retirement income and protect workers and their families against loss of income due to disability or death.

## **Employment Insurance**

Employment Insurance is a federal program which includes the following types of benefits: regular unemployment benefits, sickness benefits, maternity and parental benefits, and benefits for persons taking approved training courses or participating in job creation or job-sharing projects. To qualify, the claimant must have ceased receiving employment income and have worked a minimum number of weeks or hours of insurable employment over the preceding period.

## **Social assistance**

Social assistance covers many provincial and municipal income supplements to individuals and families. It is usually provided only after all other possible sources of support have been exhausted.

## **Workers' compensation**

Workers' compensation is provided to protect all full-time and part-time employees from loss of salary due to work accidents or occupational diseases and help them to pay their medical expenses and other costs.

## **Goods and Services Tax/Harmonized Sales Tax credit**

Introduced in conjunction with the Goods and Services Tax in 1990, it is intended to offset the GST/HST for lower income families and individuals. In Nova Scotia, New Brunswick, and Newfoundland and Labrador it is called the Harmonized Sales Tax Credit because the administration of the tax is combined with the provincial sales tax. Included is the federal Relief Heating Expenses paid in 2001.

## **Provincial/territorial tax credits**

Included here are refundable tax credits other than those for children (included with child tax benefits). Some are designed to help low income individuals and families to pay property taxes, education taxes, rent and living expenses, and so on. Provincial sales tax credits such as the Quebec Sales Tax Credit and the Newfoundland and Labrador HST Credit are included. The Quebec abatement, although refundable, is not included here but rather with income taxes. These credits are given to the family member with the highest net income.

## **Other government transfers**

This includes government transfers not included elsewhere, mainly any other non-taxable transfers. In SLID, these amounts are included with "Other income". This is partly because the coverage of any transfers not taxed through the income tax system is low. There may be under-reporting of these transfers, which are mainly collected using an open question in SLID interviews. Nonetheless, the types of transfers which have come under this heading include: training program payments not reported elsewhere, the Veteran's pension, pensions to the blind and the disabled, regular payments from provincial automobile insurance plans (excluding lump-sum payments), and benefits for fishing industry employees.

## **Total income**

Total income refers to income from all sources including government transfers before deduction of federal and provincial income taxes. It may also be called income before tax (but after transfers). All sources of income are identified as belonging to either market income or government transfers.

## **Income tax**

Income tax is the sum of federal and provincial income taxes payable (accrued) for the taxation year. Income taxes include taxes on income, capital gains and RRSP withdrawals, after taking into account exemptions, deductions, non-refundable tax credits, and the refundable Quebec abatement. The

data are either taken directly from administrative records or estimated based on aggregate data from administrative records, as this yields better results than the amounts reported by interview.

### **After-tax income**

**A**fter-tax income is total income, which includes government transfers, less income tax. It may also be called income after tax. Some of the government transfers listed above are not taxable and are allocated to only one family member, depending on age, income, or gender. These include social assistance, child tax benefits, and seniors benefit. When looking at person-level data, users should be aware that these transfers are not equally divided amongst family members.

## **Family**

### **Dwelling**

**I**n general terms a dwelling is defined as a set of living quarters. A private dwelling is a separate set of living quarters with a private access. A collective dwelling may be institutional, communal or commercial in nature. Of the different types of collective dwellings, SLID covers only communal dwellings.

### **Household**

**A** household is defined as a person or group of persons residing in a dwelling. SLID defines households and families according to the living arrangements on December 31 of the reference year. Residents of Canada are also defined at those points in time.

### **Adults**

**A**dults are defined in SLID as individuals 16 or older as of December 31st of the reference year.

### **Family income**

**F**amily income is the sum of income of each adult in the family as defined above. Household income is likewise the sum of incomes of all adults in the household. Family and household membership is defined at a particular point in time, while income is based on the entire calendar year. The family members or “composition” may have changed during the reference year, but no adjustment is made to family income to reflect this change.

### **Economic family type**

“**E**conomic family type” refers to either economic families or unattached individuals. An economic family is defined as a group of two or more persons who live in the same dwelling and are related to each other by blood, marriage, common law or adoption. An unattached individual is a person living either alone or with others to whom he or she is unrelated, such as roommates or a lodger. See Family classification for more detailed groupings.

### **Census family type**

“**C**ensus family type” refers to either census families or persons not in census families. The term “census family” corresponds to what is commonly referred to as a “nuclear family” or “immediate family”. In general, it consists of a married couple or common-law couple with or without children, or a lone-parent with a child or children. Furthermore, each child does not have his or her own spouse or child living in the household. A “child” of a parent in a census family must be under the age of 25 and there must be a parent-child relationship (guardian relationships such as aunt or uncle are not sufficient).

Persons “not in census families” are those living alone, living with unrelated individuals, or living with relatives but not in a husband-wife or parent-unmarried child (including guardianship-child) relationship.

By definition, all persons who are members of a census family are also members of the same economic family.

See Family classification for more detailed groupings.

### Major income earner

This characteristic is important for the derivation of detailed family types (see Family classification). For each household and family, the major income earner is the person with the highest income before tax, with one exception: a child living in the same census family as his/her parent(s) cannot be identified as the major income earner of the census family (this does not apply to economic families).

For persons with negative total income before tax, the absolute value of their income is used, to reflect the fact that negative incomes generally arise from losses “earned” in the market-place which are not meant to be sustained. In the rare situations where two persons have exactly the same income, the older person is the major income earner.

### Family classification

SLID uses the major income earner to classify families.

**Table B. Classification of family types**

<b>Economic families (or Census families), 2 persons or more</b>
Elderly families
Married couples
Other elderly families
Non-elderly families
Married couples without children
No earner
One earner
Two earners
Two-parent families with children
No earner
One earner
Two earners
Three or more earners
Married couples with other relatives
Lone-parent families
Male lone-parent families
Female lone-parent families
No earner
One earner
Two or more earners
Other non-elderly families
<b>Unattached individuals (or Persons not in census families)</b>
Elderly male
Non-earner
Earner
Elderly female
Non-earner
Earner
Non-elderly male
Non-earner
Earner
Non-elderly female
Non-earner
Earner

### **Elderly family**

The major income earner is aged 65 or over.

### **Non-elderly family**

The major income earner is under age 65.

### **Married couples/spouses**

Married couples, including legally married, common-law and same-sex relationships, where one of the spouses is the major income earner.

### **Children**

A child or children (by birth, adopted, step, or foster) of the major income earner under age 18. Other relatives may also be in the family.

### **Lone-parent family**

Includes at least one child as defined above. Families where the parent is 65 years or older are excluded.

### **Relative**

A person related to the major income earner by blood, marriage, adoption or common-law.

### **Other relative**

A person in the economic family who is not the major income earner nor his/her spouse or child under age 18.

## **Analytical concepts**

### **Current dollars versus constant dollars**

“Current dollars” are what we usually mean when we refer to a currency in the current time period. The term “constant dollars” refers to dollars of several years expressed in terms of their value (“purchasing power”) in a single year, called the base year. This type of adjustment is done to eliminate the impact of widespread price changes.

Current dollars are converted to constant dollars using an index of price movements. The most widely used index for household or family incomes, provided that no specific uses of the income are identified, is the Consumer Price Index (CPI), which reflects average spending patterns by consumers in Canada.

The following table shows the annual rates of the Consumer Price Index. To convert current dollars of any year to constant dollars, divide them by the index of that year and multiply them by the index of the base year you choose (remember that the numerator contains the index value of the year you want to move to). For example, using this index, \$10,000 in 1997 would be \$10,548 in 2000 constant dollars ( $\$10,000 \times \frac{113.5}{107.6} = \$10,548$ ).

Text table 1

**Consumer price index, annual rates, 1992=100**

1981	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991	1992	1993
58.9	65.3	69.1	72.1	75.0	78.1	81.5	84.8	89.0	93.3	98.5	100.0	101.8
1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004		
102.0	104.2	105.9	107.6	108.6	110.5	113.5	116.4	119.0	122.3	124.6		

**Earners/Income recipient**

An earner is a person who received income from employment (wages and salaries) and/or self-employment during the reference year. The term income recipient is generally used for someone who received a positive (or negative) amount of income of any given type.

**Mean income (average income)**

The mean or average income is computed as the total or "aggregate" income divided by the number of units in the population. It offers a convenient way of tracking aggregate income while adjusting for changes in the size of the population.

There are two drawbacks to using average income for analysis. First, since everyone's income is counted, the mean is sensitive to extreme values: unusually high income values will have a large impact on the estimate of the mean income, while unusually low ones, i.e. highly negative values, will drive it down. (See also Recipients versus non-recipients and Negative values.) Secondly, it does not give any insight into the allocation of income across members of the population. To examine allocation of income, measures such as Percentiles or Gini coefficients may be used.

**Recipients versus non-recipients (zero values)**

For every table showing average incomes, it must be kept in mind whether non-recipients of that type of income are included or excluded from the population. In the case of total family income, the difference from including or excluding units with zero income is small since there are very few such families. However, if one is interested in the average amount of individual self-employment earnings, the value will be quite different if one includes those persons who were not self-employed.

**Negative values**

Negative income amounts can arise in two ways: net losses from self-employment (expenses exceed receipts), or net investment losses (losses exceed gains). As with zero values, negative values can have a large impact on results. In general, the published income tables treat negative values no differently than positive values, but there are a few exceptions: for the calculation of both Gini coefficients and the low income gap, negative values are converted to zeroes; and in the derivation of the major income earner of a family or household, the absolute value is used instead (see Major income earner).

**Percentiles**

Income percentiles, like quintiles and deciles, are a convenient way of categorizing units of a given population from lowest income to highest income for the purposes of drawing conclusions about the relative situation of people at either end or in the middle of the scale. Rather than using fixed income ranges, as in a typical distribution of income, it is the fraction of each population group that is fixed.

First, all the units of the population, whether individuals or families, are ranked from lowest to highest by the value of their income of a specified type, such as after-tax income. Then the ranked population is

divided into five groups of equal numbers of units, called quintiles. Analogously, dividing the population ranked by income into ten groups, each comprising the same number of units, produces deciles.

Most analyses should be carried out on the people of different percentiles within one population distribution. Care should be taken in making comparisons between percentiles that resulted from different distributions, because any difference in either the population or the income concept used to rank units could have a large effect. It is probable that both the income ranges represented by each percentile and the people making up each percentile will be different.

### **Median income**

The median income is the value for which half of the units in the population have lower incomes and half has higher incomes. To derive the median value of income, units are ranked from lowest to highest according to their income and then separated into two equal-sized groups. The value that separates these groups is the median income (50th percentile).

Because the median corresponds exactly to the midpoint of the income distribution, it is not, contrary to the mean, affected by extreme income values. This is a useful feature of the median, as it allows one to abstract from unusually high values held by relatively few people.

Since income distributions are typically skewed to the left – that is, concentrated at the low end of the income scale – median income is usually lower than mean income.

### **Implicit rate of government transfers or taxes**

The implicit rate of government transfers or taxes is a way of showing the relative importance of transfers received or taxes paid for different families or individuals. This concept is similar, but not identical, to the effective rate of taxation. For a given individual or family, the effective rate is the amount of transfers/taxes expressed as a percentage of their market income, total income, or after-tax income. The implicit rate for a given population is the average (or aggregate) amount of transfers/taxes expressed as a percentage of their average (or aggregate) income.

### **Family size adjustment (equivalence scale)**

When comparing family incomes to study such things as income adequacy or socio-economic status, one often wants to take family size and composition into account—the income amount itself is not sufficient to understand a family's financial well-being without knowing how many people are sharing it. In general, two approaches have been used to help with the analysis of family income. One is to produce data by detailed family types, so that within a given family type, differences in family size are not significant. In fact, many income measures have been crossed by detailed family types in the published tables. The other way to take into account family size and composition is to adjust the income amount by an adjustment factor.

The simplest method is to use per capita income, that is, to divide the family income by the family size. A limitation of per capita income, however, is that it tends to underestimate economic well-being for larger families as compared to smaller families. This is due to the fact that it assumes equal living costs for each member of the family, but some costs, primarily those related to shelter, decrease proportionately with family size (they may also be lower for children than for adults). For example, the shelter costs for an adult married couple with no children are arguably not much more than those for an adult living alone.

To take such economies of scale into account, it is common to use an “equivalence scale” to adjust family incomes. Instead of implicitly assuming equal costs for additional family members as the per capita approach does, the equivalence scale is a set of decreasing factors assigned to the first member, the second member, and so on. The adjusted income amount for the family is obtained by dividing the family's income by the sum of the factors assigned to each member.

There is no single equivalence scale in use in Canada. The one used in the published income tables and in concepts such as the low income measure (LIM) has, however, achieved a high degree of acceptance. In this equivalence scale, the factors are as follows:

- the oldest person in the family receives a factor of 1.0;
- the second oldest person in the family receives a factor of 0.4;
- all other family members aged 16 and over each receive a factor of 0.4; and
- all other family members under age 16 receive a factor of 0.3.

Other equivalence scales in use include:

#### OECD scale

- the oldest person in the family receives a factor of 1.0;
- all other family members aged 14 and over each receive a factor of 0.7;
- all other family members under age 14 receive a factor of 0.5.

#### Modified OECD scale

- the oldest person in the family receives a factor of 1.0;
- all other family members aged 15 and over each receive a factor of 0.5;
- all other family members under age 15 receive a factor of 0.3.

Square root of family size (this is a close approximation to the LIM equivalence scale, particularly for families with 6 members or less).

#### **Gini coefficient**

The Gini coefficient measures the degree of inequality in the income distribution. Gini coefficients are published for market income, total income and after-tax income, and are used to compare the uniformity of income allocation between different income concepts, across different populations or within the same population over time.

Values of the Gini coefficient can range from 0 to 1. A value of zero indicates income is equally divided among the population with all units receiving exactly the same amount of income. At the opposite extreme, a Gini coefficient of 1 denotes a perfectly unequal distribution where one unit possesses all of the income in the economy. A decrease in the value of the Gini coefficient can, by and large, be interpreted as reflecting a decrease in inequality, and vice versa. As a rough rule of thumb when using data from SLID at the Canada level: an absolute difference of 0.01 or less between two Gini coefficients is considered statistically significant.

## **Low income definitions**

### **Low Income Cut-offs (LICOs)?**

Low income cut-offs (LICOs) are established using data from the Family Expenditure Survey, now known as the Survey of Household Spending. They convey the income level at which a family may be in straitened circumstances because it has to spend a greater proportion of its income on necessities than the average family of similar size. Specifically, the threshold is defined as the income below which a family is likely to spend 20 percentage points more of its income on food, shelter and clothing than the average family. There are separate cut-offs for seven sizes of family – from unattached individuals

to families of seven or more persons – and for five community sizes – from rural areas to urban areas with a population of more than 500,000.

The first step in the production of a set of low income cut-offs is to calculate the average proportion of income that a family spends on food, shelter and clothing. The 1992 Family Expenditure Survey found that, on average, families spend 44% of their after-tax income (and 35% of their total “before-tax” income) on these necessities. Then, 20 percentage points are added, giving 64% of after-tax income. This is done on the grounds that a family spending more than this proportion of its income on necessities is significantly worse off than the average family. The final step is to look at the distribution of income by expenditure and determine, using a regression line, the level of income at which a family tends to spend 20 percentage points more than the average on the necessities of food, shelter and clothing.

### **Rebasing and indexing the LICOs**

Over time, Canadian families have spent a smaller percentage of their income on the necessities of food, shelter and clothing. This relationship between families’ income and spending is associated with a specific point in time, i.e. the year of the expenditure survey used to derive the cut-offs. That particular year is referred to as the base year for the set of cut-offs.

After having calculated LICOs in the base year, cut-offs for other years are obtained by applying the corresponding Consumer Price Index (CPI) inflation rate to the cut-offs from the base year – the process of indexing the LICOs.

### **Low income rate and low income gap**

To determine whether a person (or family) is in low income, the appropriate LICO (given the family size and community size) is compared to the income of the person’s economic family. If the economic family income is below the cut-off, all individuals in that family are considered to be in low income. In other words, “persons in low income” should be interpreted as persons who are part of low income families, including persons living alone whose income is below the cut-off. Similarly, “children in low income” means children who are living in low income families. Overall, the low income rate for persons can then be calculated as the number of persons in low income divided by the total population. The same can be done for families and various sub-groups of the population; for example, low income rates by age, sex, province or family types.

The low income gap is the amount that the family income falls short of the relevant low income cut-off. For example, a family with an income of \$15,000 and a low income cut-off of \$20,000 would have a low income gap of \$5,000. In percentage terms this gap would be 25%. The average gap for a given population, whether expressed in dollar or percentage terms, is the average of these values as calculated for each unit. For the calculation of this low income gap, negative incomes are treated as zero.

### **Use of after-tax and before-tax LICOs**

Statistics Canada produces two sets of low income cut-offs and their corresponding rates—those based on total income (i.e., income including government transfers, before the deduction of income taxes) and those based on after-tax income. Derivation of before-tax versus after-tax low income cut-offs are each done independently. There is no simple relationship, such as the average amount of taxes payable, to distinguish the two types of cut-offs.

Although both sets of low income cut-offs continue to be available, Statistics Canada prefers the use of the after-tax LICOs. The before-tax rates only partly reflect the entire redistributive impact of Canada’s tax/transfer system. It is therefore logical that the low income rate is higher on a before-tax basis than on an after-tax basis.

### **Low Income Measures (LIM)**

For the purpose of making international comparisons, the LIM is the most commonly used low income measure. Unlike the low income cut-offs, which are derived from an expenditure survey and then compared to an income survey, the LIMs are both derived and applied using a single income survey. The LIM is a fixed percentage (50%) of median adjusted family income, where “adjusted” indicates that family needs are taken into account. See the paragraph Family size adjustment (equivalence scale) for more information.

The LIMs are calculated three times; using market income, before-tax income, and after-tax income. They do not require updating using an inflation index because they are calculated using an annual survey of family income.

### **Market basket measure (MBM)**

Social Development Canada (formerly Human Resources Development Canada) has collaborated with the provincial and territorial ministries of social services to develop the Market Basket Measure (MBM) of low income. The approach is to cost out a basket of necessary goods and services including food, shelter, clothing and transportation, and a multiplier to cover other essentials. The results define thresholds that represent levels of income needed to cover the cost of the basket.

The same argument that can be made for using after-tax low income rates can be made for using after-tax income to compare to the MBM thresholds. That is, a measure of well-being should take into account what is actually available to spend. The income concept that is used for comparisons with the MBM thresholds goes even further than after-tax income by also subtracting from total income other non-discretionary expenses such as support payments, work-related child care costs and employee contributions to pension plans and to Employment Insurance.

Statistics Canada collects the data necessary to produce rates based on Social Development Canada’s Market Basket Measure.

## **Comparisons between data up to 1995 and data since 1996**

Starting with reference year 1996, the Survey of Labour and Income Dynamics (SLID) replaced the annual Survey of Consumer Finances (SCF) as the official source of family income in Canada. This means that data up to and including 1995 are drawn from SCF (last conducted for reference year 1997), and data for 1996 and onwards are drawn from the SLID (which was introduced in 1993).

Different surveys will produce slightly different estimates on the same topics due to a variety of factors. Every attempt was made to minimize and monitor these differences between the two income surveys, while nonetheless making some important improvements in survey practices. Before replacing the SCF series with SLID, a careful study was done on the overlapping reference years, particularly the years 1996 and 1997, as SLID only acquired its full sample size in 1996. The results of the study are contained in the Income Statistics Division research paper, *A Comparison of the Results of the Survey of Labour and Income Dynamics (SLID) and the Survey of Consumer Finances (SCF) 1993-1997: Update* (75F002MIE1999007). All ISD research papers are available free of charge on the Statistics Canada internet site ([www.statcan.ca](http://www.statcan.ca)).

In short, it was found that the two surveys told essentially the same story for all of the main income concepts. It is still possible, nonetheless, that for some characteristics the data trends could reveal a “break” as a result of the change in survey. Such a break would likely appear as a noticeable upward or downward shift in a data series between the years 1995 and 1996. It represents a change in the data which is attributable to the two surveys having different samples and different methods (such as the use of tax data in the case of SLID), rather than a true change in the characteristics of the population. Users are advised to take note of the following survey differences which are known to exist and to have had an impact on the data trends at some detailed levels.

## Better coverage of small income amounts

One notable improvement that occurred as a result of new survey techniques introduced in SLID is better coverage of small income amounts received by respondents. It has been observed in surveys conducted by questionnaire that respondents tend to forget or neglect small income amounts they received in the past. This means an underestimation of income in general, and in particular, it means that many people who received a small amount of income instead report no income at all (there are differences, however, depending on whether the income concept includes or excludes government transfers).

The use of administrative income tax files in SLID for the majority of sample respondents means that there is considerably better coverage of non-zero amounts of income, and in general, a greater number of recipients of most kinds of income. Another technique used by SLID which may have improved coverage is that, even for respondents who report income by interview instead of via their tax records, there are two chances to prompt them for income sources, and therefore a greater likelihood of capturing an amount. This is because some income concepts are touched on in the January interview and then covered in the May interview, where it is possible to remind the respondent of a positive response in January. The types of income for which such “dependent interviewing” is used are earnings (from employment or self-employment), employment insurance benefits, social assistance, and workers’ compensation.

## Detailed family types

The standard published “detailed family types” for economic families have changed in one regard. In the SCF, they are derived with reference to the “head of family”. In SLID, the same categories are used but in reference to the “major income earner”. SLID dropped the concept of head of family entirely, as it has little relevance in a modern context. But some sort of prioritization of people within a family is useful to uniquely identify the type of family, even if it is somewhat arbitrary.

The change in family concepts resulting from the transition from SCF to SLID has not affected data produced for the entire population of families consisting of two or more persons. However, for some of the detailed family types, the estimated number of families underwent a one-time increase or decrease between 1995 and 1996. Without drawing conclusions about the precise net effects of these changes, the following points can be made.

First, whereas the previous definition always gave husbands the status of head of family rather than wives, with the major income earner concept there is no distinction by sex, and it is possible for the wife to qualify. Since it still holds that wives are on average younger than husbands at least for older couples, this has caused a shift from elderly families to non-elderly families.

Second, the head of family concept gave preference to parents over their adult children and, where there is no husband-wife or parent-child relationship in the family, it gave preference to older members over younger ones. Now, younger adults are much more likely to qualify as major income earners than they did as heads of families. As a result, we see significant decreases in the number of “other elderly families” and “married couples with other relatives”, and a large increase in the number of “other non-elderly families”. (See the section “Family definitions” for the precise definitions of family types.)

## Comparisons with previous editions

Data from different editions are not directly comparable. Every edition has some modifications done on data. The modification which is applied every year is the expression of all dollars amounts in constant dollars of the latest reference year. (See “Current dollars versus constant dollars”.)

The Survey of Labour and Income Dynamics uses estimates of the target population - which are derived independently from the survey – as benchmarks for producing survey estimates. These population estimates start with a Census and are then updated using administrative data to reflect the current

population of Canada. Using these population counts reduces the sampling error and coverage bias of survey estimates. It also provides consistency of estimates across household surveys. Accurate population numbers are crucial in determining estimates from a sample survey like SLID. In order to translate the results of the survey into population estimates, each individual in the sample is assigned a weight indicating the number of persons in the population represented by that sample member.

Periodically, the weights used in the survey are updated to reflect the availability of new population benchmarks provided by a new census and new annual inter-censal estimates. When this happens, the weights are revised historically in order to maintain a consistent time series. Methodological improvements in the derivation of weights may also be implemented in a weight revision.

There was a historical weight revision in 2000 that was carried out on data back to 1980, such that figures for the entire time series changed. Traditionally, weights are derived using population benchmarks by province, age and sex. Since the 2000 weight revision, the weights in SLID also respect population benchmarks by household size and economic family size. The most recent historical weight revision for the Survey of Labour and Income Dynamics occurred with the release of data for 2003.

### **2003 historical revision**

The release of the 2003 data is accompanied by a historical revision for 1990 to 2002 due to an update of the survey weights in both the Survey of Labour and Income Dynamics (SLID) and the Survey of Consumer Finances (SCF). The weighted data now take into account not only new population projections based on the 2001 Census of Population, but also valuable information on the overall distribution of wages and salaries—a major component of income—in Canada. A lot of research has been conducted on the new weighting methodology and it is felt that as a result of this, the ability of these surveys to accurately represent income levels in Canada has been given a new boost. The quality of the survey data on other topics has also been improved.

The impacts of the historical revision, which was applied to the data back to 1990, are quite similar for all years, so that the trends shown by the data remain very similar. But the actual levels of estimates do change in many situations. The estimates are in fact much closer to other reliable sources of information on similar topics.

The 2003 historical revision also incorporates revised 1992-base low income cut-offs (LICOs) resulting from a historical re-weighting of the 1992 Family Expenditure Survey.

### **Why we introduced new income adjustments in the weighting**

Research has shown that historically, Statistics Canada's household income surveys have tended to under-represent people with very low levels of earnings or no earnings, as well as people with very high earnings, while over-representing people who are more in the middle of the earnings distribution. Average and aggregate earnings and incomes have been over-estimated as a result.

The System of National Accounts (SNA) corrected a comparable problem by applying aggregate adjustments to the estimates. In a household survey like SLID, such an approach is not possible; instead, the method for correcting the biases in estimation was to make differentiated adjustments to the weights attached to each of the respondents.

Statistics Canada over the past few years did a lot of investigation to develop the best possible options for improving the estimates through improved weighting techniques. We tested several options and evaluated their stability over several years of data, to ensure that no new biases would result from the corrections and to ensure that we chose the best possible option currently available. Finally, the evaluations included comparisons with other independent sources of information like the Census and the System of National Accounts. Apart from the time required to test and evaluate the changes, there is no particular reason why Statistics Canada introduced these changes now instead of next year or last year.

In addition to our usual adjustments to population estimates we concluded that adding the T4 administrative files (employer remittances of payroll taxes) were the best benchmark statistics available with which to adjust the weights in SLID. We believe that the quality of the T4 files is high and that historically, the quality of files is sufficient to allow this adjustment to be made back to 1990.

The improvements to survey weights during the 2000 and 2003 historical revisions have been part of a comprehensive project at Statistics Canada to improve the weighting strategies in the main annual surveys on income, expenditures, and wealth. The project is now complete for the Survey of Labour and Income Dynamics and the Survey of Consumer Finances.

### **What the new weighting methods consist of**

Survey weights are the numbers assigned to each of the sample respondents so that together they sum to the target population and sub-groups of that population. To do this as accurately as possible, the weights are often adjusted to be in line with other independent sources of information. The Census of Population, with its related population projections, is the source for the benchmark demographic statistics used to adjust the survey weights. The revised weights now take into account population projections from the 2001 Census.

The additional benchmark statistics that are now used to adjust survey weights come from the annual T4 file from Canada Revenue Agency (CRA), which is a compilation of employer remittances for the purposes of payroll taxes. SLID obtains tabulated statistics from the T4. Specifically, the statistics being used concern the total number of people in each province who had earnings from paid employment during the year and the amounts they made relative to each other, called the earnings distribution. The number and earnings of self-employed people are not included. It is important to add that aggregated data are used from this file and no matching of individual information between the T4 file and the SLID and SCF data files is done.

The annual T4 files cover all employees, regardless of whether they filed a T1 tax return. The wages and salaries of employees represent a very high proportion of all income received by individuals. Although many people in the population do not have this type of income, the T4 data allow us to correct biases not only for the wage-earning population but also for the rest of the population, because it provides an accurate way of determining the presence or absence of wages.

This is not the first time that a survey has used the T4 files from CRA in order to better represent the distribution of incomes in the population. The Survey of Household Spending implemented similar weighting methods using T4 data in its 1999 historical revision.

As evidence that the additional calibration of weights has helped to better reflect the distribution of incomes in the SLID, the estimates are now more similar to related estimates from other sources. These sources are not only the T4 file, but also the T1 file (personal income tax file), the Census, and the System of National Accounts.

### **What was the impact of the revision on the estimates?**

The change from the 1996 Census to the 2001 Census for population estimates and projections affected mainly the period after 1996.

The historical revision had little impact on the trends shown by SLID since 1996 and SCF up to 1995. This is because the addition of weight adjustments based on income had a similar impact for all years. The weight revision was taken back to 1990; consequently, only between the years 1989 and 1990 is there potentially a disturbance in the data series that could affect the representation of trends.

The level estimates, however, did change in many cases. The precise impacts can be seen by comparing the data that were published before the historical revision with those published in May of 2005. Note however that previously published dollar figures must be compared with their revised values using either current dollars or consistent constant dollars in both cases. Be aware also that rounding of dollar values in published tables may affect the precision of comparisons.

Finally, the SLID low income estimates changed as a result not only of the new weights in SLID, but also the new low income cut-offs with which family incomes in SLID are compared.

### **Examples of how the estimates changed**

- In general, the number of people in the ten provinces with earnings from employment, also referred to as wages and salaries because it excludes self-employment, was adjusted downwards. However this is not true in all range categories of earnings: there are more people now in the lowest and highest earnings categories, but fewer in the middle of the distribution.
- Due to the predominant downward revisions in the number of persons by earnings classes and despite the upward revision in the number of high-wage earner adults, average and median wages and salaries usually decreased with the revision.
- Since wages and salaries constitute a large part of incomes, most estimates of market income, total income, and after-tax income were also adjusted downwards.
- As a consequence of lower wages and salaries, government transfers generally increased, including social assistance benefits, child benefits, and refundable sales tax credits such as the GST/HST Credit.
- The weight revisions due to the new income adjustments based on the T4 file affected estimates concerning children and adults up to age 64 relatively more than estimates concerning seniors, due to the fact that income from employment makes up a smaller portion of seniors' incomes.
- Consistent with the increases in the number of people with no earnings or very low earnings, the low income rates for persons and families (on an after-tax basis) generally underwent an upward revision in all years. Again the rates for senior-led families and individuals were less affected.
- Consistent with the increases in the number of people at the very low and very high ends of the earnings distribution, and the decrease in the number of people in the middle of the distribution, certain measures of income inequality (Gini coefficient, ratio of 5<sup>th</sup> to 1<sup>st</sup> quintile) generally increased.
- The revision also affected characteristics which are not directly related to incomes. For example, the following estimates are now closer to the estimates of the 2001 **Census**:
  - Level of educational attainment in Canada.
  - Rate of home ownership versus renting.

For more details of these impacts and more information on the new weighting methodology, please refer to the free research paper, Survey of Labour and Income Dynamics: 2003 historical revision, Statistics Canada, (forthcoming publication)

# *Methodology*

## **Survey universe**

SLID is a household survey that covers all individuals in Canada, excluding residents of the Yukon, the Northwest Territories and Nunavut, residents of institutions and persons living on Indian reserves or in military barracks. Overall, these exclusions amount to less than three percent of the population.

## **The sample**

The samples for SLID are selected from the monthly Labour Force Survey (LFS) and thus share the latter's sample design. The LFS sample is drawn from an area frame and is based on a stratified, multi-stage design that uses probability sampling. The total sample is composed of six independent samples, called rotation groups, because each month one sixth of the sample (or one rotation group) is replaced.

The SLID sample is composed of two panels. Each panel consists of two LFS rotation groups and includes roughly 17,000 households. A panel is surveyed for a period of six consecutive years. A new panel is introduced every three years, so two panels always overlap.

## **Weighting**

The estimation of population characteristics from a survey is based on the premise that each sampled unit represents, in addition to itself, a certain number of unsampled units in the population. A basic survey weight is attached to each record to indicate the number of units in the population that are represented by that unit in the sample.

For each reference year, SLID produces two sets of weights: one is representative of the initial population (the longitudinal weights) while the other is representative of the current population (the cross-sectional weights). For the production of the cross-sectional weights, SLID combines two independent samples and assigns a probability of selection to individuals who joined the sample after the panel was selected.

Two types of adjustment are applied to the basic survey weights in order to improve the reliability of the estimates. The basic weights are first inflated to compensate for non-response. The non-response adjusted weights are then further adjusted to ensure that estimates on relevant population characteristics would respect population totals from sources other than the survey.

The first set of population totals used for SLID is based on Statistics Canada's Demography Division population counts for different age/sex groups as well as counts by household and family size at the provincial level. These annual population totals are based in large part on totals from the Census of population.

The second set of totals is derived from Canada Revenue Agency (CRA) administrative data (T4 file) and is intended to ensure that the weighted distribution of income (based on wages and salaries) in the data set matches that of the Canadian population.

The switch from 1996 to 2001 Census-based population totals for recent years and the use of T4 information from CRA were introduced with the release of data for 2003. SCF estimates from 1990 to 1995 and SLID estimates from 1996 to 2002 were revised back to 1990 at the same time.

## Cross-sectional representation in SLID

Each longitudinal sample, or “panel” in SLID initially constitutes a representative cross-sectional sample of the population. However, because the real population changes each year, whereas by design the longitudinal sample does not, the sample must be modified to properly reflect these changes to the composition of the population. This is done by adding to the sample all new people in the population who are found to be living with the initial respondents (and likewise dropping them from the sample if they leave at later time-points).

Any original respondents who leave the target population (by moving abroad, into institutions, etc.) are given a zero weight for cross-sectional purposes. In this way, the cross-sectional sample, composed of the original respondents minus those who left the target population plus those who have entered it, is virtually fully representative of the population at each subsequent time-point. The missing group is composed of persons who have newly entered the target population and are not living with anyone who was in the target population when the most recent panel was selected. However, since SLID introduces a new panel every three years, this group is quite small.

## Data quality

There are two types of errors inherent in sample survey data, namely, non-sampling errors and sampling errors. The reliability of survey estimates depends on the combined impact of non-sampling and sampling errors. For more detailed information on data quality indicators see the research paper (Data quality in the 2003 Survey of Labour and Income Dynamics (SLID) 75F0002MIE2005004.pdf ) available free of charge on the Statistics Canada internet site ([www.statcan.ca](http://www.statcan.ca)).

## Non-sampling errors

Non-sampling errors generally result from human errors such as simple mistakes, misunderstanding or misinterpretation. The impact of randomly occurring errors over a large number of observations will be minimal. Errors occurring systematically can, on the other hand, have a major impact on the reliability of estimates. Considerable time and effort is invested into reducing non-sampling errors in SLID.

Non-sampling errors may arise from a variety of sources such as coverage, response, non-response and processing errors.

**Coverage error** arises when sampling frame units do not exactly represent the target population. Units may have been omitted from the sampling frame (under-coverage), or units not in the target population may have been included (overcoverage), or units may have been included more than once (duplicates). Undercoverage represents the most common coverage problem.

**Slippage** is a measure of survey coverage error. It is defined as the percentage difference between control totals (Census population projections) and weighted sample counts. Slippage rates for household surveys are generally positive because some people that should be enumerated are missed. Slippage rates have been revised back to 1996 using the 2001 Census population projections. According to the numbers in the table below, in 2003, SLID covered 86.5% of its target population. SLID estimation procedures use Census population projections to compensate for determined slippage.

Rates are also available upon request for sex, province and age groupings.

Text table 1

Slippage rates in SLID

	1997	1998	1999	2000	2001	2002	2003
	percent						
Canada	8.4	9.0	8.4	9.5	10.6	12.4	13.5

**Response errors** may be due to many factors, such as faulty questionnaire design, interviewers' or respondents' misinterpretation of questions, or respondents' faulty reporting. Great effort is invested in SLID to reduce the occurrence of response error. Measures undertaken to minimize response errors include the use of highly-skilled and well-trained interviewers, and supervision of interviewers to detect misinterpretation of instructions or problems with the questionnaire design. Response error can also be brought about by respondents who, willingly or not, provide inaccurate responses.

Income data are especially prone to misreporting, as income is a sensitive issue and includes many items with which respondents are not always familiar. Therefore, respondents are provided with information by mail prior to the interview, informing them of the income related questions. This gives them time to consult documents and have information available at the time of the interview. For respondents who grant Statistics Canada permission to access their tax files (the majority of respondents), SLID collects income data directly from administrative files. This procedure reduces misreporting of income in the SLID.

**Non-response errors** occur in sample surveys because not all potential respondents cooperate fully. The extent of non-response varies from partial non-response to total non-response.

**Total non-response** occurs when the interviewer is unable to contact the respondent, no member of the household is able to provide information, or the respondent refuses to participate in the survey.

Response is calculated at the household level. A household is considered to be "respondent" if at least one of its members responds to either the January or the May interview. There is the additional stipulation that the information on the household's composition cannot be missing for more than one year.

Total household non-response is handled by adjusting the basic survey weight for individuals within responding households to compensate for individuals in nonresponding households.

Nonresponding members (if any) within responding households who did not respond to one or both of the collection phases will have final data that is either shown as "missing" on the final database or imputed, depending on the variable (see partial non response section for details on imputation).

The importance of the non-response error is unknown but in general this error is significant when a group of people with particular characteristics in common refuse to cooperate and where those characteristics are important determinants of survey results. The bias introduced by non-response increases with the differences between respondent and non-respondent characteristics. Methods employed to compensate for non-response make use of information available for both respondents and non-respondents in an attempt to minimize this bias.

High response rates are essential for the data quality of any survey and thus considerable effort is invested to encourage effective participation from SLID respondents.

Cross-sectional response rates, given in Table F, range between 78.3% (2003) and 86.0% (1996)."

## Text table 2

### Response rate in SCF (1990-1995) and SLID (1996-2002)

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
	percent													
Response Rate	79.0	80.0	80.7	80.0	79.5	82.1	86.0	84.1	82.7	82.7	79.2	79.1	79.0	78.3

**Partial non response** occurs when the respondent does not understand or misinterprets a question, refuses to answer a question, or is unable to recall the requested information. Imputing missing values compensates for this partial non-response.

Income data are imputed using previous years' data updated for any changes in circumstances. In the absence of previous years' data, data is imputed using the "nearest neighbour" technique, in which a respondent with certain similar characteristics becomes the "donor" for the imputed value.

Amounts received through certain government programs, such as child tax benefits, the Goods and Services Harmonized Sales Tax Credit, and the Guaranteed Income Supplement, are also derived from other information. Data obtained from the tax route are complete and do not need imputation.

**Processing errors** can occur at various stages in the survey: data capture, editing, coding, weighting or tabulation. The computer-assisted collection method used for SLID reduces the chance of introducing capture errors because checks for consistency and completeness of the data are built into the computer application. To minimize coding, weighting or tabulation errors, diagnostic tests are carried out periodically. These tests include comparisons of results with other data sources.

### Sampling errors

Sampling errors occur because inferences about the entire population are based on information obtained from only a sample of the population. The results are usually different from those that would be obtained if information were collected from the whole population. Errors due to the extension of conclusions based on the sample to the entire population are known as sampling errors. The sample design, the variability of the population characteristics measured by the survey, and the sample size determine the magnitude of the sampling error. In addition, for a given sample design, different methods of estimation will result in sampling errors of different sizes.

### Standard error and coefficient of variation

A common measure of sampling error is the standard error (SE). The standard error measures the degree of variation introduced in estimates by selecting one particular sample rather than another of the same size and design. The standard error may also be used to calculate confidence intervals associated with an estimate (Y). Confidence intervals are used to express the precision of the estimate. It has been demonstrated mathematically that, if the sampling were repeated many times, the true population value would lie within the confidence interval  $Y \pm 2SE$  95 times out of 100 and within the narrower confidence interval defined by  $Y \pm SE$ , 68 times out of 100. Another important measure of sampling error is given by the coefficient of variation, which is computed as the estimated standard error as a percentage of the estimate Y (i.e.,  $100 \times SE / Y$ ).

To illustrate the relationship between the standard error, the confidence intervals and the coefficient of variation, let us take the following example. Suppose that the estimated average income from a given source is \$10,000, and that its corresponding standard error is \$200. The coefficient of variation is therefore equal to 2%. The 95% confidence interval estimated from this sample ranges

from \$9,600 to \$10,400, i.e.  $\$10,000 \pm \$400$ . Thus it is assumed with a 95% degree of confidence that the average income of the target population is between \$9,600 and \$10,400.

The bootstrap approach is used for the calculation of the standard errors of the estimates. For more information on standard errors and coefficients of variation, refer to the Statistics Canada publication, (Methodology of the Canadian Labour Force Survey) available on the Statistics Canada internet site ([www.statcan.ca](http://www.statcan.ca)).

## Suppression rules

Suppression rules, or data reliability cutoffs, are currently established based on the sample size that underlies the estimate. In general, a sample size of 25 observations is required for the estimate to be published. Depending on the type of estimate, this rule can vary slightly. These rules help protect the confidentiality of survey respondents and ensure the reliability of estimates.

Text table 3

### Suppression rules for various estimates

Estimate	Supress IF:
<b>Percentage, distribution, proportion/shares</b>	
<ul style="list-style-type: none"> <li>• % under the low-income cutoff (LICO)</li> <li>• Income distribution</li> <li>• Proportion of families with income=0</li> </ul>	Denominator* sample size < 25 or Denominator* sample size < 100 and numerator sample size < 5
<b>Ratios</b>	
<ul style="list-style-type: none"> <li>• female/male earnings</li> </ul>	Numerator sample size < 25 or Denominator sample size < 25
<b>Quintiles (shares, means and upper income limits)</b>	
<ul style="list-style-type: none"> <li>• shares of income by quintile</li> <li>• average income by quintile</li> <li>• upper income limits</li> </ul>	sample size of all quintiles/5 < 25 or upper income limit for upper income quintile or total of quintiles
<b>Other estimates</b>	
<ul style="list-style-type: none"> <li>• Counts</li> <li>• Mean</li> <li>• Medians</li> <li>• Gini coefficients</li> </ul>	sample size < 25

\*The denominator sample size refers to the sample size of the total estimate from which the distribution, percentage, proportion or share is derived.

## Quality Indicators

Quality indicators (QIs) are based on the estimate's coefficient of variation (CV) and suppression rules. At present, quality indicators are applied mostly to the 2003 estimates with the exception of a

few longitudinal tables. For years where the quality indicators are not available, they are omitted. The following symbols are used:

Text table 4

**Quality rules**

<b>Estimates for:</b>	
<b>QI Code</b>	<b>Description</b>
<b>Most current year</b>	
A	Excellent (CV between 0 and 2%)
B	Very good (CV between 2% and 4%)
C	Good (CV between 4% and 8%)
D	Acceptable (CV between 8% and 16%)
E	Use with caution (CV greater than or equal to 16% )
<b>All years</b>	
F	Too unreliable to be published
.	Not available for a complete reference period
..	Not available for a specific reference period
...	Not applicable
p	Preliminary
r	Revised
x	Suppressed to meet the confidentiality requirements of the Statistics Act

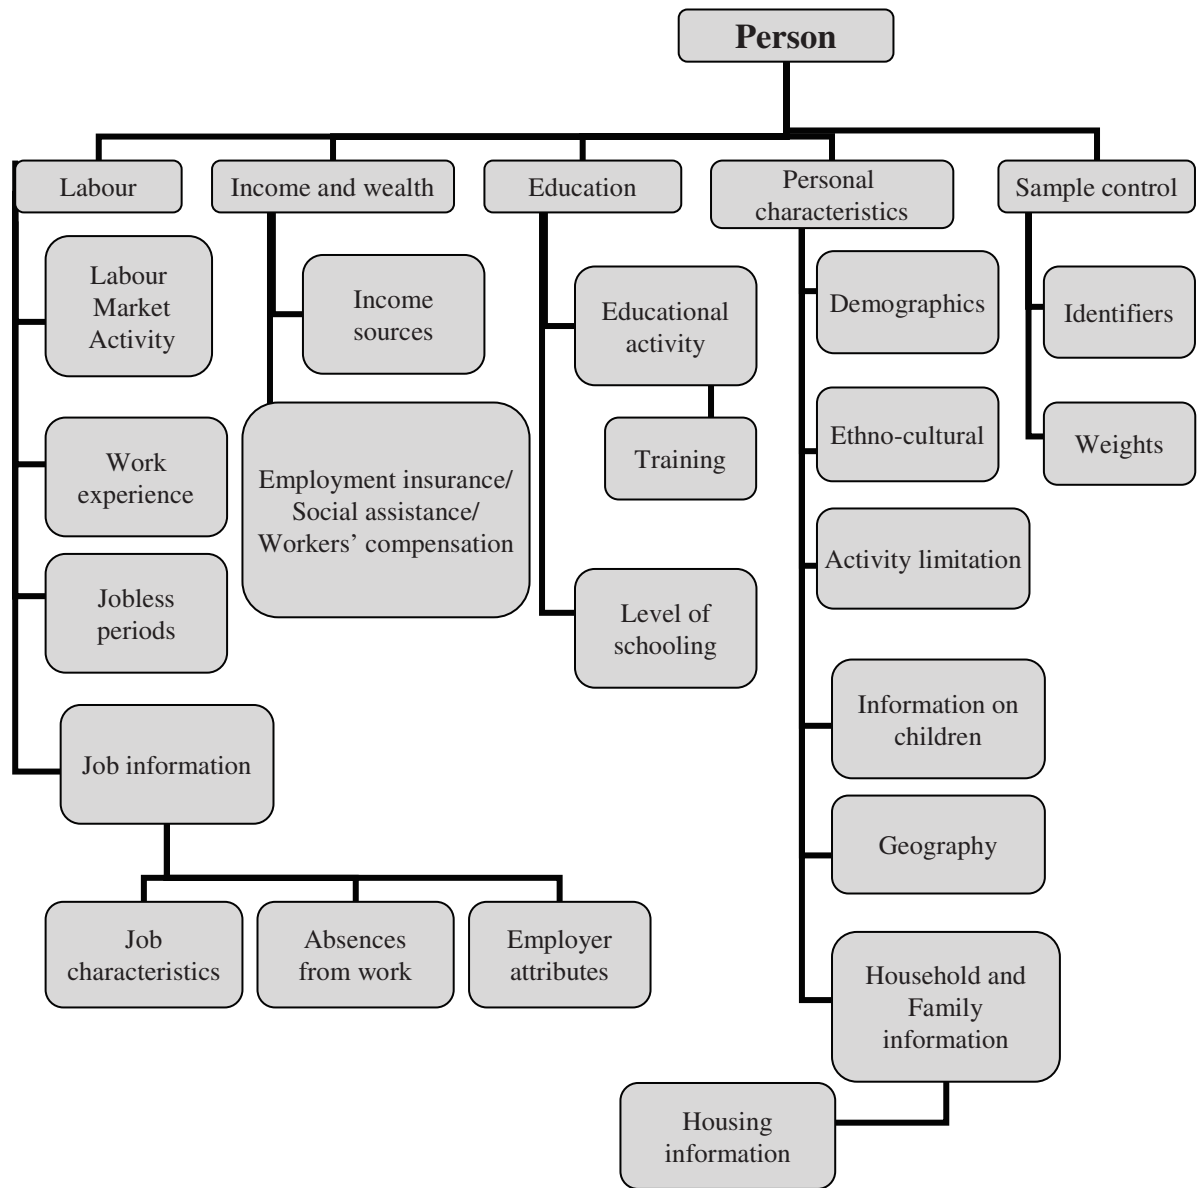

## *Survey content*

SLID collects data on a wide range of topics. Some are inherently “dynamic”, involving transitions and spells, while others have important explanatory value.

The content themes are shown in Figure :

- Labour
- Income and wealth
- Education
- Personal characteristics
- Sample control

For more detailed information on survey variables, refer to the SLID electronic data dictionary.

## Labour

### Labour market activity

- major activity during year
- employment/unemployment spells (start and end dates, durations)
- weekly labour force status
- total weeks of employment, unemployment and inactivity by year
- multiple job-holding spells

- work absence spells

**Work experience**

- years of full-time and part-time employment
- years of experience in full-time, full-year equivalents

**Jobless periods**

- job search during spell
- dates of search spells
- desire for employment
- reason for not looking

**Job characteristics\***

- start and end dates, first date ever worked for this employer
- wages
- work schedule (hours and type)
- benefits
- union membership
- occupation
- supervisory and managerial responsibilities
- class of worker
- tenure
- how job was obtained
- reason for job separation

\* Job characteristics are updated annually for up to six jobs per year with dates of change recorded.

**Absences from work\***

- absence dates
- reason
- paid or unpaid

\* Absences lasting one or more weeks are collected on the first and last absence each year, for each employer.

**Employer attributes**

- industry
- firm size

- public or private sector

## **Income and Wealth**

### **Income source**

- annual information on about 25 income sources
- market income
- government transfers
- taxes paid
- after-tax income

### **Receipt of Employment Insurance/social assistance/workers compensation\***

- Employment Insurance
- social assistance
- workers' compensation

\* Amount and timing of monthly benefits received from each source.

## **Education**

### **Educational activity**

- enrolled in a credit program, months, weeks and hours attended
- type of institution
- full-time or part-time student
- certificates received (if applicable)
- job-related training courses, seminars, workshops and conferences

### **Level of schooling/educational attainment\***

- years of schooling
- degrees and diplomas
- major field of study

\* Updated annually

## **Personal characteristics**

### **Demographics**

- year of birth/age
- sex

- duration of current marital status
- year/age at first marriage

#### **Ethno-cultural**

- ethnic background
- member of an employment equity designated group
- mother tongue
- date of immigration
- country of birth
- parents' schooling and place of birth

#### **Activity limitation**

- annual information on activity limitations and their impact on working
- satisfaction with work

#### **Information on children**

- number of children born, raised
- year and person's age when first child born

#### **Geography and geographic mobility**

- economic region or census metropolitan area of current residence
- size of community
- moved during year
- move dates
- reason for move
- nature of move (full household/household split)

#### **Household and family information\***

- key characteristics of other household/family members (e.g., age, sex, relationship, income, annual hours worked)
- relevant low-income cutoff
- family events (marriage, separation, deaths, births)
- **Housing information:**
- type of dwelling
- dwelling condition
- characteristics of dwelling

- ownership / mortgage / rent
  - payments / costs / rent inclusions
  - housing suitability indicator
  - Shelter costs to income ratio
- \* Annual summary information, e.g., size, type

## **Sample control**

### **Identifiers**

- person
- household
- economic family
- census family

### **Weights**

- cross-sectional
- cross-sectional adjusted for labour non-response
- longitudinal
