Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

Abstract

Data Quality in the 2002 Survey of Labour and Income Dynamics

The Survey of Labour and Income Dynamics (SLID) is a longitudinal survey initiated in 1993. The survey was designed to measure changes in the economic well-being of Canadians as well as the factors affecting these changes.

Sample surveys are subject to errors. As with all surveys conducted at Statistics Canada, considerable time and effort is taken to control such errors at every stage of the Survey of Labour and Income Dynamics. Nonetheless errors do occur. It is the policy at Statistics Canada to furnish users with measures of data quality so that the user is able to interpret the data properly. This report summarizes a set of quality measures that has been produced in an attempt to describe the overall quality of SLID data. Among the measures included in the report are sample composition and attrition rates, sampling errors, coverage errors in the form of slippage rates, response rates, tax permission and tax linkage rates, and imputation rates.

1. Introduction

The Survey of Labour and Income Dynamics (SLID) is a longitudinal survey initiated in 1993. The survey was designed to measure changes in the economic well-being of Canadians as well as the factors affecting these changes. The target population consists of all persons living in Canada with the following exclusions: persons living in Yukon, the Northwest Territories, and Nunavut, persons living on Reserves, persons living in institutions, and military personnel living in barracks.

The SLID sample is comprised of 2 panels. Each panel remains in the survey for 6 consecutive years and a new panel is rotated in every 3 years. In January following the reference year, SLID sample households are contacted by telephone interviewers. Demographic information is collected for every person in the household. Complete survey data are collected for every person in the household 16 years or older. Questions are asked on labour (labour market activity, work experience, jobless spells and job information), educational attainment and income sources. At the end of the January interview, respondents are informed that they will be contacted again in May when they will be asked to supply data on income as well as certain expense items. However, the respondent may elect to grant permission to Statistics Canada to retrieve all the data required from the T1 tax file, thereby avoiding the necessity of a second interview. Collection of income data is deferred until May so that the respondent will be more familiar with the required data (having just filed an income tax return).

Although originally designed as a longitudinal survey, SLID has always maintained the capability of producing cross-sectional estimates. This cross-sectional aspect took on new importance with the cancellation of the Survey of Consumer Finance after the 1997 reference year. At this time SLID became the primary source of cross-sectional household and family income data.

All persons who are members of selected SLID households in the beginning of the first year of a panel's existence are longitudinal sample persons for SLID. As such, it is these individuals that are followed longitudinally. Any (non-longitudinal) person living in a household with a longitudinal person is referred to as a cohabitant. Cohabitants living with cross-sectionally eligible longitudinal persons will also be cross-sectional sample persons.

For more information about survey concepts, definitions and design please refer to Statistics Canada publication: "*Survey of Labour and Income Dynamics - A survey overview*", <http://www.statcan.ca:8096/bsolc/english/bsolc?catno=75F0011X>

Sample surveys are subject to errors. As with all surveys conducted at Statistics Canada, considerable time and effort is taken to control such errors at every stage of the Survey of Labour and Income Dynamics. Nonetheless errors do occur. It is the policy at Statistics Canada to furnish users with measures of data quality so that the user is able to interpret the data properly. This report summarizes quality measures that have been produced in an attempt to describe the overall quality of SLID data.

2. Sample composition/attrition

Although originally designed as a longitudinal survey, SLID also has the capability of producing cross-sectional estimates. Every non-longitudinal person living with a longitudinal respondent is also asked to participate in the survey. Such persons are called cohabitants. Table 2.1 and 2.2 show the composition of the SLID sample by province and by census metropolitan area (CMA) respectively, in terms of longitudinal sample persons who respond, longitudinal responding persons that are ineligible cross-sectionally (such as deceased, institutionalized and those who have moved outside the country), and responding cohabitants. Historical tables can be found in appendix 1.

The cross-sectional SLID sample coverage is maintained through the addition of cohabitants each year. The one exception is immigrants who arrive after the beginning of a panel and before the start of the next one and move into their own households, this introduces a small amount of under coverage. The longitudinal sample, however, is subject to attrition. Attrition is the gradual loss of respondents each year through the life of the panel. Table 2.3 shows the respondent status for persons originally selected as longitudinal respondents. In table 2.3 the responding longitudinal sample size is comprised of the in-scope respondents, the individuals who have moved to Yukon, North-West Territories or Nunavut, the individuals who have moved outside Canada, the institutionalized individuals and the deceased individuals.

Table 2.1 - Sample composition in SLID by province, 2002

1. This includes individuals who are deceased, institutionalized and those who have moved outside the country.

2. This information is only available for those individuals who are cross-sectionally eligible.

Table 2.3 - Status of longitudinal persons, reference year 2002

Longitudinal status	Panel 03	Panel 04
In scope (respondents)	32,922	33,792
In scope (nonrespondents)	3,970	7,936
Moved to Yukon, NWT, Nunavut	14	3
Moved outside Canada	386	105
Institutionalized	437	141
Deceased	1,010	255
Removed from sample ¹	4,941	0
Duplicate person/error ²	3	0
Total	43,683	42,232

1. Respondents are removed from the sample for one of two reasons. If entire households have refused for 2 consecutive cycles they are said to be hard refusals and no further attempts are made to enumerate these households. As well after two years households that were not traced are not sent out for further attempts at collection.

2. Respondents who were erroneously included in the household in the beginning of the first year of a panel's existence.

3. Sampling errors

Sampling errors occur because inferences about the survey population are based on data from a sample of that population rather than the entire population. The sample design, the variability of the characteristic being measured, and the sample size will all contribute to the magnitude of the sampling error.

The standard error is a common measure of sampling error. The standard error measures the degree of variation introduced in estimates by selecting one particular sample rather than another of the same size and design. Another widely used measure of the sampling error is the coefficient of variation (CV), which is the estimated standard error expressed as a percentage of the estimate.

In SLID, the bootstrap approach is used for the calculation of standard errors. This is a resampling method of variance estimation, often used when dealing with estimates from a complex sample design. Table 3.1 shows CV levels at the provincial and national level for a sample of key SLID estimates.

Table 3.1 - National and provincial coefficients of variation (%) for selected SLID variables

Variable	N.L.	P.E.I.	N.S.	N.B.	Que.	Ont.	Man.	Sask.	Alta.	B.C.	Canada

Counts of employed people	2.2	1.7	1.4	1.6	1.1	0.9	1.3	1.6	1.1	1.5	0.5

4. Coverage errors

To produce good survey estimates, it is necessary that a survey sample adequately represent the survey population. To ensure proper coverage, SLID weights are adjusted using census population projections as control totals. The slippage rate is a measure of the percentage difference between these census projections and the survey estimate using weights prior to the application of this slippage related adjustment. More precisely, slippage is computed as

$$slippage_c = \frac{(CP_c - \sum_{k \in S_c} w_{kc})}{CP_c} * 100$$

where Class C is the group or class for which we want to calculate slippage rates. For example at a detailed level the groups are based on province, sex and age group.
 CP_c is the census population projection for class C
 w_{kc} is the survey weight for k^{th} responding unit in class C
 S_c is the set of responding sample households in class C

Slippage rates for household surveys are generally positive because of frame under coverage.

Table 4.1 shows slippage rates at the person level by province and by age/sex groupings.

As a comparison we will look at the person level slippage rates for the Labour Force Survey (LFS) by province. We will look at the slippage rates from the LFS at the beginning of the panel for each panel in tables 4.2 and 4.3. These rates are the rates associated with the rotation groups used by SLID.

Slippage rates were also computed at the household level and are summarized in Table 4.4. For slippage rates for previous reference years, see Appendix 2.

Table 4.1 - Person level slippage rates (%) by province/sex/age group

5. Response rates

Since SLID has taken on the role of both a longitudinal and a cross-sectional survey, respective response rates are calculated. Cross-sectional response rates are calculated both at the person level and at the household level. Since sample persons have the option of giving tax permission thereby avoiding the May interview, it is possible to have complete data for income with no actual contact made during the reference year. Because of this the definition of a nonrespondent is not straightforward.

If all persons in non-responding January households are also nonrespondent in May, then these persons (and households) are nonrespondent.

For those persons in non-responding January households for whom we have tax data, it is determined whether the person is in the same household as the previous year (as of December 31). If the household is different this means the respondent has split from the original household. Since we have no information at all on the household composition of the new household, such persons are defined to be nonrespondent.

Persons in non-responding January households for whom we have May data and for whom the household has not changed since the previous year, are considered nonrespondents if the household was a non-responding household in the previous January. Since updates to household composition are collected in January, this means that the household composition has not been updated for 2 consecutive years. Persons in households that have been nonrespondent in 2 consecutive January collections are therefore considered to be nonrespondents to SLID.

The person level response rates are calculated by dividing the number of cross-sectionally eligible respondents to the January and/or May interviews by the total number of cross-sectionally eligible people. An assumption is made that nonrespondents are still in the target population unless there is evidence to the contrary. As a result this may somewhat underestimate response rates.

Table 5.1 - Cross-sectional person response rates (%) (age>15)

Type	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002
Response	92.2	88.4	85.2	85.4	83.4	81.8	81.6	78.0	77.8	77.8
Non-response	7.8	11.6	14.8	14.6	16.6	18.2	18.4	21.9	22.2	22.2

A household is considered a respondent household if at least one person in that household is considered a respondent. Household response rates are calculated by dividing the number of cross-sectionally eligible responding households by the total number of cross-sectionally eligible households. Once again an assumption is made; non-responding households are assumed to be still in the target population unless there is evidence to the contrary. As a result this may somewhat underestimate response rates.

Nonresponse can potentially introduce a bias in the data. A bias is created if characteristics of respondents differ from those of nonrespondents and this difference has an impact on the variable being studied. It is difficult to determine whether nonresponse is introducing bias, because there is a limited amount of information for nonrespondents.

Figure 5.1 shows the household response rates by province.

Figure 5.1 - Cross-sectional household response rates by province (%)

Table 5.2 shows the person response rates by phase. ‘Respondent to labour interview’ and ‘Respondent to income interview’ are the percentages of those who responded to only the labour (January) or income (May) interviews respectively whereas the ‘Respondent to both interviews’ is the percentage of all those who responded in full or in part to both interviews.

Table 5.2: Cross-sectional person response rates by phase (%)

Type	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002

Due to the conceptual difficulty in defining a longitudinal household, only person level longitudinal response rates are calculated. Table 5.3 shows person level longitudinal response rates by panel. These rates are calculated by dividing the number of longitudinal respondents by the original number of longitudinal persons selected in that panel. Figure 5.2 shows the longitudinal non-response by panel and wave.

Table 5.3 - Longitudinal person response rates (%) (all ages)

6. Tax permission rates

There are two interviews every year: in January the interview is about activities such as working, going to school, looking for work or retirement. The second interview in May is about income, but it is not necessary if the respondent gives Statistics Canada permission to obtain the required data from tax records. The tax source should provide consistent data of high quality and so a high permission rate should ensure good quality survey income estimates. The respondent is asked for this permission at the end of the January interview. If permission is not given, the respondent is contacted again in May. At this time the respondent is once again asked if he/she would prefer to give permission to access tax records. If permission is not provided, the interview proceeds.

Table 6.1 shows permission rates by panel for each phase of the survey. The option to give tax permission was given for the first time in the May collection for the 1994 reference year. Prior to this, all income data were collected through interview.

Percentages in the table are based on the number of respondents over the age of 15 who are cross-sectionally eligible. Permission rates in reference year 2000 are the same for both January and May because there was no May interview in that year.

Table 6.1 - SLID permission rates (%) by panel

1. Permission was asked for the first time in May 1994

7. Tax linkage rates

While respondents may grant Statistics Canada permission to use their tax data, they are not asked for their Social Insurance Number (SIN). Without a SIN to identify SLID respondents on the tax file, it is necessary to perform a linkage operation to find a respondent's SIN. The generalized record linkage system (GRLS) developed at Statistics Canada is used to perform this linkage.

After preprocessing of both the tax file and the SLID file to ensure compatible formatting of all match variables, a direct match is performed using 7 key matching variables. These matching variables are: Sex, province, soundex¹ code for surname, surname, date of birth, postal code and first initial. The SLID record can have no missing data for key matching variables. Output for the direct match is manually reviewed for errors where a SLID record matches to more than one tax record, where more than one tax record matches to a SLID record, and where the first given name is not the same on the 2 sources (only first initial is used in the tax match). The match rate on the direct match is approximately 55 percent.

The unmatched records are then run through a statistical match. Pockets² for matching are defined. The files are segmented into pockets with sex, province and surname soundex code defining a pocket. Every record within a pocket on the SLID file is compared with every record within the same pocket on the tax file. Factors of importance are assigned for full agreement, partial agreement, and disagreement. These factors are numeric values and are used to evaluate the likelihood that a pair of records (one from SLID and one from tax) represent the same person. Factors are defined for each of the matching variables. Thresholds are defined whereby records are determined to be definite matches if their total factor is greater than the upper threshold or definite non-matches if their total factor is below the lower threshold. Manual verification is done to ensure the

1. Soundex is a name coding routine used in order to remove any common spelling errors from the surnames of respondents. This encoding is done based on the sound of the surname.

2. Pockets are groups of individuals on both the tax file and the SLID file with the same sex, province and soundex code.

quality of the matches. Figure 7.1 gives the percentage of the SLID sample giving tax permission for which a SIN can be found. Since some respondents who give tax permission have not filed a tax return not all cases for which a SIN is found will result in successful tax linkages. Figure 7.2 gives tax linkage rates for those in the SLID sample for which we were successful in finding a SIN.

Figure 7.1: Percentage of SINS found

Figure 7.2: SLID/tax linkage rates

8. Imputation rates

To compensate for non-responding households in the SLID sample, a non-response adjustment is applied to SLID weights. However, partially responding households are kept in the sample and any income data that is missing for individuals within responding households is imputed. These individuals may require complete imputation of all income variables or they may require only certain fields to be imputed. Imputation rates in SLID may be thought of as a measure of partial non-response in the survey.

Imputation of income variables in SLID is done using a nearest neighbour approach. A set of basic consistency rules is defined and for a given record requiring imputation a set of consistent donors is identified. A set of matching variables, each of which are correlated with the variables to be imputed, is also defined. Through combined use of both a score function (for categorical matching variables) and a distance function (for numeric matching variables), the most similar consistent donor record is identified and used to impute data for the record.

The score function used in SLID income imputation is:

$$s(X, Y) = \sum_{k=1}^K p_k I(X_k, Y_k), \quad \text{where } I(X_k, Y_k) = \begin{cases} 1 & \text{if } X_k = Y_k \\ 0 & \text{if not.} \end{cases}$$

Note that p_k is a number allowing us to assign more or less importance to the matching variable k . X_k is the value of the receiver's variable k and Y_k is the value of the donor's variable k .

The distance function used in SLID income imputation is the same as the function used in the generalized edit and imputation system (GEIS). Suppose we have two records X and Y . The distance between the two is defined as:

$$d(X, Y) = \max_{j=1}^J |u_j(X) - u_j(Y)|$$

Where $u_j(X)$ is the function of the rank³ of X_j :

$$u_j(X) = \frac{\text{rank}(X_j)}{n_j + 1}.$$

J represents the number of quantitative variables used to calculate the distance, X_j represents the value of the quantitative variable j of the record X and n_j is the number of records with a valid value for this variable. When several records have the same value of the variable j , they are assigned a mean rank. Excluding these cases of equality the $u_j(\cdot)$ are uniformly distributed along the interval (0, 1).

The percentage of persons within responding SLID households that were subject to total or partial imputation is shown in Table 8.1. Recall that a responding SLID household is

3. The rank is a method by which a numeric variable can be normalized. This way a numeric variable with a range from 0 to 9 and a numeric variable with a range from -999999 to 999999 have the same level of importance in the distance function.

one in which at least one household member has responded partially or completely in the January and/or the May component of the survey.

Table 8.2 compares the proportion of records from tax to those collected in the telephone interview.

In total eighteen income variables are imputed during SLID income imputation. Many individuals require only partial imputation. Partial imputation is when one or more income items is imputed with some information being supplied by the individual. In table 8.3 we compare the percentage of tax data records requiring imputation to the percentage of records for which data is collected through the telephone interview. The need for partial imputation is determined after combining responses from both the January and May interviews. Inconsistencies are corrected through the imputation process. Table 8.3 also shows the percentage of individuals subject to partial imputation who require between one and seventeen variables to be imputed.

Table 8.1 - Persons requiring imputation of income variables, by province in 2002

Province	Total imputation ¹	Partial imputation ²	No imputation

2 – 9 variables imputed	0.2	22.9	0.0	2.2
10 – 17 variables imputed	0.0	4.2	90.6	15.8

1. Records that are not linked to Tax and without a May (Income) interview. Some of these records are partially imputed based on the information collected during the January interview

In 2002, new housing content relevant for housing research and policy development was added to SLID in cooperation with the Canada Mortgage and Housing Corporation (CMHC). The survey now collects information for the following sub-populations beginning with the 2002 reference year: the need for repairs (as determined by the dwelling occupant); the principal heating fuel of the dwelling; and whether a farm or home business is operated from the property. Also from homeowners the amount of regular mortgage payments; the amount of annual property taxes; and whether the dwelling is part of a registered condominium is collected. From renters the following is collected: the amount of monthly rent, what amenities are included in the rent (*e.g.*, heat, water, electricity); and whether the rent is subsidised by government or an employer.

The above information is in addition to information about home ownership and type of dwelling (since 1994) and information on the presence of a mortgage and the number of bedrooms in dwellings (since 1999).

Because of non-response to specific questions, imputation of housing related content was introduced in SLID in 2002. Two methods of imputation were used, longitudinal imputation and cross-sectional donor imputation. The cross-sectional donor imputation uses a similar method to that used in the income imputation. Making use of the score function describe above. Table 8.4 shows the percentage of responding SLID households that were subject to total or partial imputation.

In total twenty housing variables are imputed during SLID housing imputation. Many households require only partial imputation. Table 8.5 shows the break down of those requiring partial imputation.

9. Rounding of income data

A small percentage of SLID income data comes from data collected in a telephone interview in May. While data obtained from the tax file is thought to be consistent for the most part, the quality of data coming from collection is not known. While some respondents may refer to tax forms and give precise amounts, it is possible that many of the responses given are estimates or approximations, which therefore are stated in hundreds or thousands of dollars rather than precise dollars and cents

To test for the possible presence of rounding, distributions of each of the last 4 digits of reported variables were produced. One would normally expect the distribution to be approximately uniform with the digits 0 to 9 each comprising about 10 percent of the distribution. A prevalence of zeroes in the last digit would indicate rounding to the nearest 10, in the second last digit rounding to 100, etc. Table 9.1 shows the distribution of each of these digits for all reported values greater than ten thousand of the variable wages and salaries from both collected data (e.g. collected by interview) and tax data. Table 9.2 shows the prevalence of zeroes in each of the last 4 digits for all reported non-zero values for a selection of SLID variables.

Table 9.1 - Distribution of the last 4 digits of wages and salaries for collected data versus tax data (greater than 10,000)
