Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

Abstract

In order to provide a holographic or complete picture of low income, Statistics Canada is implementing an approach that uses three complementary low income lines: the Low Income Cut-offs (LICOs), the Low Income Measures (LIMs) and the Market Basket Measure (MBM). While the first two lines were developed by Statistics Canada, the MBM is based on concepts developed by Human Resources and Skills Development Canada. Though these measures differ from one another, they give a generally consistent picture of low income status over time. None of these measures is the best. Each contributes its own perspective and its own strengths to the study of low income, so that cumulatively, the three provide a better understanding of the phenomenon of low income as a whole. These measures are not measures of poverty, but strictly measures of low income.

The LICOs are based on the relationship between the incomes and the consumption patterns of Canadian households as observed in 1992. The LICOs have been very widely used in Canada since the 1970s. The LIM is based solely on the distribution of household income across the Canadian population and is intended as a reference for international comparisons. Statistics Canada has been producing the LIM for more than 15 years. With this release, a different approach in calculating the LIM is introduced which is aligned with latest international standard. Finally, the MBM defines low income in relation to the cost of a predefined set of goods and services. The price of this "basket" of goods and services takes regional differences in the cost of living into account.

This publication incorporates a detailed description of the methods used to arrive at each of these measurements. It also explains how base years are defined and how LICOs are updated using the Consumer Price Index. Because the LICOs only depend on the annual Consumer Price Index, they can be produced as soon as the CPI is available (January following the reference year). The LIMs and the MBM depend on other survey products that are available much later. Consequently, they can only be produced 12 to 16 months after the end of the reference year. For these reasons, this report contains LICOs up to 2009, but LIMs and MBM up to 2008 only.

Introduction

Statistics Canada has a long history of publishing data on the low income of Canadians. The low income cut-offs (LICOs) were first published in 1967 as part of the 1961 Census monograph series and are by far Statistics Canada's most established and widely recognized approach to estimating low-income cut-offs. LICOs are income thresholds below which families devote a larger share of income to the necessities of food, shelter and clothing than the average family would.

Following the practice of many international organizations, Statistics Canada began to publish before- and after-tax low income measures (LIMs) in 1991. LIMs are particularly convenient for making international comparisons, since estimating the cut-offs requires only data on household¹ incomes within a country. As such, they require no adjustments using exchange rates or purchasing power parity indexes as would be necessary to make meaningful comparisons of absolute levels of income between countries.

The Market Basket Measure (MBM) was developed by Human Resources Development Canada (HRSDC) to represent a standard of living that is a compromise between subsistence and social inclusion that reflects differences in living costs across the country (Hatfield, Pyper and Gustajtis 2010). The thresholds are produced for a reference family of two adults and two children for all sizes of area of residence in each province and for several cities. While HRSDC is responsible for defining the components of the basket and the related concepts, Statistics Canada is responsible for the costing the components and producing low income statistics.

Media, researchers and policy-makers interested in measures of low income are typically concerned with the extent to which individuals in the population are living in poverty. Unfortunately, defining poverty is far from straightforward. The underlying difficulty is that poverty is a question of social consensus, defined for a given point in time and in the context of a given country. Decisions on what defines poverty are subjective and ultimately arbitrary². Given this, Statistics Canada has always referred to the low income lines as indicators of the extent to which some Canadians are less well-off than others based solely on income and as such, are low income and not poverty measures.

Other statistical organizations are also sensitive to the use of the word 'poverty'. Eurostat refers to its measure (similar to the LIM) as an 'at risk of poverty' measure. In the United States, where an official poverty measure exists, the poverty rates are qualified as being calculated according to a specified definition, allowing that other measures are possible.

The purpose of this document is to provide the dollar cut-offs used to define the low income population. Low income status can be determined using family or household income. The family concept used is the economic family, that is, all persons living in the same dwelling and related by blood, marriage, common-law relationship or adoption. A household is defined as a person or group of persons residing in a dwelling

-
1. Previously, LIMs were calculated at the economic family level. Beginning with this release, LIMs are calculated at the household level to meet the international standard.
 2. Refer to 'On poverty and Low income' (Fellegi) and 'Describing the Distribution of Income: Guidelines for Effective Analysis' (Skuterud, Frenette, and Poon) for a more detailed discussion on poverty and low income.

Low income cut-offs

What are the LICOs?

The low income cut-offs (LICOs) are income thresholds below which a family will likely devote a larger share of its income on the necessities of food, shelter and clothing than the average family. The approach is essentially to estimate an income threshold at which families are expected to spend 20 percentage points more than the average family on food, shelter and clothing.³ The first set of published LICOs used the 1959 Family Expenditure Survey to estimate five different cut-offs varying between families of size one to five. These thresholds were then compared to family income from Statistics Canada's major income survey, the Survey of Consumer Finances (SCF)⁴, to produce low income rates.

Today, Statistics Canada continues to use precisely this approach to construct LICOs, with the exception that cut-offs now vary by 7 family sizes and 5 different populations of the area of residence. This additional variability is intended to capture differences in the cost of living between rural and urban areas.⁵

How are LICOs calculated?

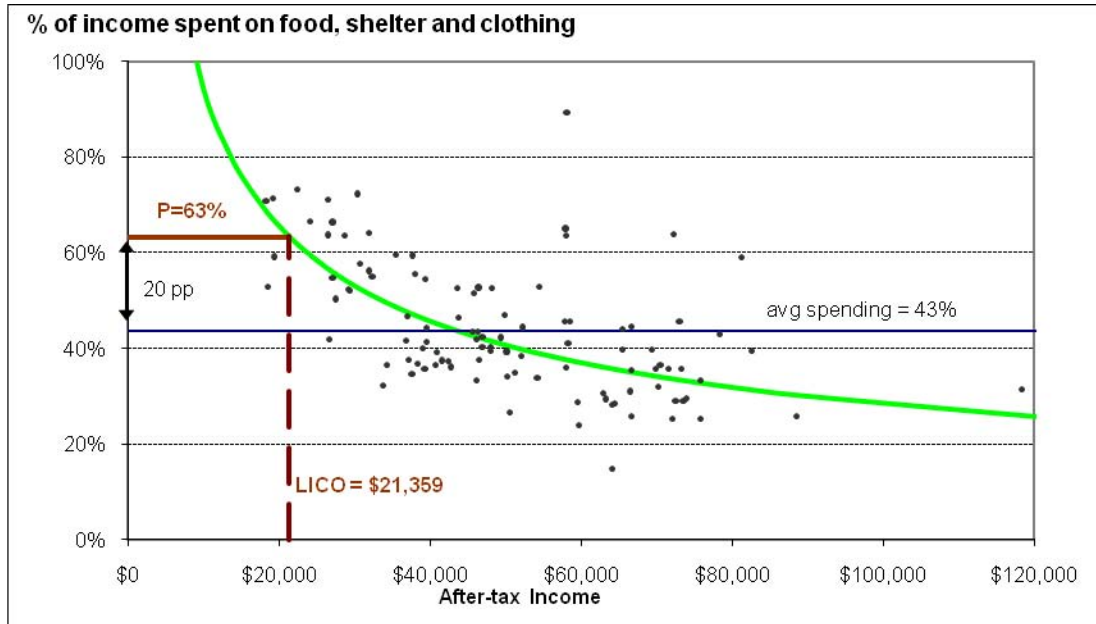

As mentioned previously, a LICO is an income threshold below which a family will likely devote a larger share of its income to the necessities of food, shelter and clothing than an average family would. According to the most recent base for LICOs, the 1992 Family Expenditures Survey, the average family spent 43% of its after-tax income on food, shelter and clothing. Figure 1 shows the calculation of a LICO using the example of a family of four living in an urban community with a population between 30,000 and 99,999. The 63% line represents the average proportion of after-tax income that all families (regardless of size) spent on food, shelter and clothing in 1992 (i.e. 43%) plus the 20 percentage point margin. The dots on the chart show the actual observed proportion of income spent by four-person families in medium-sized cities on necessities, according to the 1992 Family Expenditure Survey. A regression line is fitted to this distribution and the intersection of that curve and the 63% line gives the LICO—in this case, \$21,359.^{6 7 8}

This process is carried out for seven family sizes and five community sizes and results in a table of 35 cut-offs. This operation is done twice: once for before-tax cut-offs, once for after-tax cut-offs.

-
3. Twenty percentage points are used based on the rationale that a family spending 20 percentage points more than the average would be in "straitened circumstances".
 4. Starting with data for 1996, the Survey of Labour and Income Dynamics (SLID) replaces the Survey of Consumer Finances (SCF).
 5. The LICOs were revised in early 2005 to incorporate revised weights from the 1992 Family Expenditure Survey, which were part of the 2003 Survey of Household Spending historical revision.
 6. The model is the following: the logarithm of spending on food, shelter and clothing is a function of the logarithm of income, family size and size of the area of residence.
 7. It can clearly be seen that as income increases, the proportion spent on food, shelter and clothing decreases. In this case, points to the left of the intersection point between the regression curve and 63% line represent situations where more than 63% of after-tax income is spent on necessities
 8. All dollar values are expressed in current dollars.

Figure 1

Calculation of an after-tax LICO

Rebasing and indexing the LICOs

Over time, Canadian families have spent a smaller percentage of their income on the necessities of food, shelter and clothing. This relationship between families' income and spending is associated with a specific point in time, i.e. the year of the expenditure survey used to derive the cut-offs. That particular year is referred to as the base year for the set of cut-offs. In order to account for changing spending patterns, Statistics Canada has in the past recalculated new LICOs after each subsequent Family Expenditure Survey. This process is referred to as rebasing and includes recalculating new LICOs using the method described in 'How are low income cut-offs calculated?' and the new spending data. In addition to the 1992 base, LICOs have also been based on the 1986, 1978, 1969 and 1959 Family Expenditure Surveys; although cut-offs based on 1992 are the most commonly used and are available for the income reference years from 1976 onwards.⁹

After having calculated LICOs in the base year, cut-offs for other years are obtained by applying the corresponding Consumer Price Index (CPI) inflation rate to the cut-offs from the base year – the process of indexing the LICOs. The CPI are provided at the end of this document. For example, continuing with the 1992 after-tax LICO for a family of four living in an urban community with a population between 30,000 and 99,999; to calculate the corresponding LICO for 2009, the Consumer Price Index is used as follows:

9. In 1997, the Family Expenditure Survey was replaced by the Survey of Household Spending, an annual survey. Therefore, theoretically new rebased LICOs could be produced annually (see Cotton, Webber, Saint-Pierre (1999) for more details).

$$\text{LICO}_{2009} = \text{LICO}_{1992} \times \text{CPI}_{2009} / \text{CPI}_{1992} = 21,359 \times 114.4 / 84.0 = 29,089$$

Thus for 2009, the 1992 based after-tax LICO for a family of four living in an urban community with a population between 30,000 and 99,999 is \$29,089, expressed in current dollars.

Because the LICOs only depend on the annual Consumer Price Index, they can be produced as soon as the CPI is available, that is January following the reference year.

Note that using the CPI to update the cut-offs takes inflation into account, but does not reflect any changes that might occur over time in the average spending on necessities.

Use of after-tax and before-tax LICOs

The average proportion of income that families spend on food, shelter and clothing, which figures prominently in the low income cut-offs, is undoubtedly a useful gauge of economic well-being no matter which income concept is used. The choice of after-tax income, total income or market income depends on whether one wants to take into account the added spending power that a family gets from receiving government transfers or its reduced spending power after paying taxes.

Statistics Canada produces two sets of low income cut-offs and their corresponding rates—those based on total income (i.e., income including government transfers, before the deduction of income taxes) and those based on after-tax income. Derivation of before-tax versus after-tax low income cut-offs are each done independently. There is no simple relationship, such as the average amount of taxes payable, to distinguish the two types of cut-offs.

Although both sets of low income cut-offs and rates continue to be available, Statistics Canada prefers the use of the after-tax measure.

The choice to highlight after-tax rates was made for two main reasons. First, income taxes and transfers are essentially two methods of income redistribution. The before-tax rates only partly reflect the entire redistributive impact of Canada's tax/transfer system because they include the effect of transfers but not the effect of income taxes. Second, since the purchase of necessities is made with after-tax dollars, it is logical to use people's after-tax income to draw conclusions about their overall economic well-being.

Differences in after-tax and before-tax rates

The number of people falling below the cut-offs has been consistently lower on an after-tax basis than on a before-tax basis. This result may appear inconsistent at first glance, since incomes after tax cannot be any higher than they are before tax, considering that all transfers, including refundable tax credits, are included in the definition of "before-tax" total income. However, with a relative measure of low income such as the LICO, this result is to be expected with any income tax system which, by and large, taxes those with more income at a higher rate than those with less. These "progressive" tax rates compress the distribution of income. Therefore, some families in low income before taking taxes into account are relatively better off and not in low income on an after-tax basis.

Low income measures

What is the LIM?

For the purpose of making international comparisons, the LIM is the most commonly used low income line. The use of the low income measure (LIM) was suggested in 1989 in a discussion paper written by Wolfson, Evans, and the OECD¹⁰ which discussed their concerns about the LICOs. In simple terms, the LIM is a fixed percentage (50%) of median adjusted household¹¹ income, where “adjusted” indicates that household needs are taken into account. Adjustment for household sizes reflects the fact that a household’s needs increase as the number of members increases. Most would agree that a household of five has greater needs than a household of two.

The LIMs are calculated three times; with market income, before-tax income, and after-tax income using the Survey of Labour and Income Dynamics (SLID). They do not require updating using an inflation index because they are calculated using an annual survey of household income. Unlike the low income cut-offs, which are derived from an expenditure survey and then compared to an income survey, the LIMs are both derived and applied using a single income survey.

Changes to the LIM – accounting unit, unit of analysis and equivalence scale

With this release, some changes have been made to the concepts around the Low Income Measures (Murphy, Zhang and Dionne, 2010). These changes relate to the accounting unit utilized, the unit of analysis and the equivalence scale.

In previous years, the economic family was the accounting unit in which individuals pooled income to enjoy economies of scale. However, beginning this year, the household has replaced the economic family in the LIM. The rationale for this change is twofold. Firstly, housing costs such as mortgage interest or rent and utilities are likely shared among individuals living in a dwelling, regardless if they are part of a different economic family. Secondly, the household is the international standard when analysing income distribution (The Canberra Group 2001).

In addition, a change also appears at the unit of analysis. The median is no longer calculated over the population of families or households, but over the population of individuals. Hence, each person in the population is represented by its adjusted household income. The LIM is then defined as 50% of the median of the adjusted household income observed at the person level.

Finally, the equivalence scale has been changed. In the past, the scale used by Statistics Canada was as follows:

- the oldest person in the family was assigned a factor of 1.0;
- the second oldest person in the family was assigned a factor of 0.4;
- each of the other family members aged 16 and over was assigned a factor of 0.4;
- each of the other family members under age 16 was assigned a factor of 0.3.

10. 'Statistics Canada's Low Income Cut-offs: Methodological Concerns and Possibilities' (Wolfson, Evans, and OECD).

11. A household is defined as a person or group of persons residing in a dwelling.

The adjusted income amount for the family was then obtained by dividing the family's income by the sum of the factors assigned to the family's members.

In order to ensure international consistency and to facilitate the calculation of adjusted household income, a new scale will now be used. From now on, adjusted household income will be obtained by dividing household income by the square root of the number of members in the household. Previous years' LIMs have been revised accordingly.

How is the LIM calculated?

In order to calculate the LIMs, first calculate "equivalent household income" for each household by dividing household income by its adjusted size, that is the square root of the number of persons in the household. Next, assign this adjusted household income to each individual in the population. Then determine the median of this "equivalent household income" over the population of individuals that is the amount where half of all individuals will be above it and half below. The LIM for a household of one person is 50% of this median "equivalent household income", and the LIMs for other sizes of households are equal to this value multiplied by their "equivalent household size".

Market Basket Measure (2008 base)

What is the MBM?

The MBM is based on the cost of a specific basket of goods and services representing a modest, basic standard of living. It includes the costs of food, clothing, footwear, transportation, shelter and other expenses for a reference family of two adults aged 25-49 and two children (aged 9 and 13). It provides thresholds for a finer geographic level than the LICO, allowing, for example, different costs for rural areas in the different provinces. These thresholds are compared to disposable income of families to determine low income status. Disposable income is defined as the sum remaining after deducting the following from total family income: total income taxes paid; the personal portion of payroll taxes; other mandatory payroll deductions such as contributions to employer-sponsored pension plans, supplementary health plans, and union dues; child support and alimony payments made to another family; out-of-pocket spending on child care; and non-insured but medically prescribed health-related expenses such as dental and vision care, prescription drugs, and aids for persons with disabilities.

The MBM and the MBM disposable income were designed by a working group of Federal, Provincial and Territorial officials, led by HRSDC between 1997 and 1999 (Hatfield, 2002; Michaud, Cotton and Bishop 2004). During 2009 and early 2010, it underwent a comprehensive review of both content and methodology (Hatfield, Pyper and Gustajtis 2010). The consultation process, led by HRSDC, involved officials from Provincial and Territorial governments, other federal governments and agencies including Statistics Canada and a panel of experts in low income measurement. This review process led to a rebased series of thresholds (MBM 2008 base), revised historically to 2000, the beginning of the MBM time series.

How are MBM thresholds calculated?

The MBM thresholds are calculated as the cost of purchasing the following items:

- A nutritious diet as specified in the 2008 National Nutritious Food Basket.
- A basket of clothing and footwear required by a family of two adults and two children
- Shelter cost as the median cost of a two- or three-bedroom units including electricity, heat, water and appliances
- Transportation costs, using public transit where available or costs associated with owning and operating a modest vehicle where public transit is not available.
- Other necessary goods and services.

Low income rate and low income gap

To determine whether a person is in low income, the appropriate low income line (LIL) is compared to the income of the person's family¹² (or household)¹³. If their income is below the cut-off, the individual is considered to be in low income. In other words, "persons in low income" should be interpreted as persons who are part of low income families (or households), including persons living alone whose income is below the cut-off. Similarly, "children in low income" means "children who are living in low income families (or households)". Overall, the low income rate for persons can then be calculated as the number of persons in low income divided by the total population. The same can be done for various sub-groups of the population; for example, low income rates by age, sex, or province.

After having determined that an individual is in low income, the depth of its low income can be analysed by using the amount that the person's family (or household) income falls short of the relevant low income cut-off. For example, an individual living in a family (or household) with an income of \$15,000 and a low income cut-off of \$20,000 would have a low income gap of \$5,000. In percentage terms this gap would be 25%.¹⁴ The average gap for a given population, whether expressed in dollar or percentage terms, is the average of these values as calculated for each person.

12. The family concept used is the economic family, that is, all persons living in the same dwelling and related by blood, marriage, common-law relationship or adoption.

13. When using the LICO or the MBM, the economic family is the appropriate unit. When using the LIM, the household is the appropriate unit.

14. For the calculation of this low income gap, negative incomes are treated as zero.

Table 1 Low income cut-offs (1992 base) after tax

Size of family unit	Community size

Note: After-tax LICOs were never published on a 1959 base, 1969 base, or 1978 base.

Table A.4 Low- income cut-offs (LICOs), 1986 base, before tax

Size of family unit	Community size				
	Rural areas	Urban areas			
		Less than 30,000	30,000 to 99,999	100,000 to 499,999	500,000 and over
1986	Current dollars				
1 person	8,065	9,266	10,165	10,405	11,847
2 persons	10,933	12,561	13,779	14,105	16,059
3 persons	13,896	15,966	17,514	17,928	20,412
4 persons	15,999	18,382	20,164	20,641	23,501
5 persons	17,480	20,084	22,031	22,552	25,677
6 persons	18,974	21,800	23,914	24,479	27,871
7 or more persons	20,408	23,448	25,721	26,329	29,977

Table A.5 Low- income cut-offs (LICOs), 1986 base, after tax

Size of family unit	Community size				
	Rural areas	Urban areas			
		Less than 30,000	30,000 to 99,999	100,000 to 499,999	500,000 and over
1986	Current dollars				
1 person	6,414	7,532	8,381	8,607	10,045
2 persons	8,696	10,212	11,364	11,669	13,620
3 persons	11,258	13,220	14,711	15,107	17,632
4 persons	13,242	15,550	17,304	17,769	20,739
5 persons	14,407	16,919	18,826	19,333	22,565
6 persons	15,399	18,083	20,123	20,664	24,118
7 or more persons	16,372	19,226	21,394	21,969	25,641

Annual consumer price index (CPI) for Canada, all-items (2002=100)

1960	15.5	1980	44.0	2000	95.4
1961	15.7	1981	49.5	2001	97.8
1962	15.9	1982	54.9	2002	100.0
1963	16.1	1983	58.1	2003	102.8
1964	16.4	1984	60.6	2004	104.7
1965	16.8	1985	63.0	2005	107.0
